14. ABSTRACT This program addresses basic scientific and engineering issues related to the development of power magnetic technologies. Specific research topics are addressed to support Air Force applications. The goals and expected impact of this work are to reduce the weight, heat loss, and volume of AF systems, and also to improve performance or enable new capabilities. As the development of magnetic technologies progress with time, these goals are being reached very significantly. Specific subtopics and approaches to be emphasized in this work include: study and development of magnetic tape cores, modeling and building of permanent magnet assemblies, research on exchange spring magnets, and modeling and testing of inductors.					
15. SUBJECT TERMS magnetic materials, inductors, high power electronics, high power density, generator, magnetic assemblies, rare earth magnets

FOREWORD

This report summarizes the in-house research efforts for magnetic materials and applications of the AFRL/RQQM team, covering both 6.1 and 6.2 research efforts for an 8-year period of October 2006 to October 2014. The research output of this team was significant with over 20 scientific publications. It is not reasonable to comprehensively cover such a large amount of material in a single report, so a synopsis and summary is provided instead. An introduction is given to the major research topics covered and publication references are provided for the research output that was made publically available.

PREFACE

The author would like to especially thank Dr. Ali Sayir and The Air Force Office of Scientific Research (AFOSR) and the Power and Controls Division of the Aerospace Systems Directorate (AFRL/RQQ), for their generous and consistent support of this work.

The author also thanks the current and former team members and collaborators that did the research for this effort and that this report references and highlights. The author specifically thanks Zafer Turgut, Yuhui Shen, Serhiy Leontsev, Meiqing Huang, Christina Chen, Hiroyuki Kosai and Matt Lucas for their consistently impressive work.

Magnetic components and electromachines are essential to most aerospace systems. The drive for lighter, smaller, more powerful and more efficient magnetic components and electromachines has been the impetus for this work unit.

The Department of Defense has recognized the need for advanced magnetic materials and devices and has supported research in these areas. This support has led to some major discoveries. For example, the energy product of permanent magnets has greatly increased since the 1960s due to two key discoveries by Department of Defense researchers. Air Force researchers Strnat and Hoffer developed the first rare earth cobalt magnets in the 1960s [1]. Navy researchers Koon and Das developed the first rare earth-iron-boron magnets in the early 1980s [2].

1 SUMMARY

1.1 Executive Summary of Progress and Milestones/Lessons Learned

During the years FY06-FY14 various magnetic materials and magnetic applications were investigated. These magnetic materials and magnetic applications were for power applications. These power applications include inductors, transformers, electric motors, generators, actuators and converters. Being non-power areas, this effort did not include research in sensors or data storage. Soft (temporary) and hard (permanent) magnetic materials were part of this research effort. Soft magnetic research included iron cobalt research, tape core research, and research on the basic science of soft magnetic materials. Hard magnetic material research focused on rare earth powder or flake preparation, bulk rare earth magnet fabrication, and exchange-spring magnet research. The last area of this report involves applications of magnetic materials. Two applications are described. The design, modeling and building of a permanent magnet solenoid is discussed. Second, the performance of magnetic cores for converters is discussed.

Collaborations proved very useful in this project. A cross directorate AFOSR lab task with AFRL/RX led to much high level basic science on magnetic alloys being done. Another cross directorate collaboration with AFRL/RDHP led to the development, patenting and fabrication of a permanent magnet solenoid. A cross branch effort with AFRL/RQQE led to applied research on loss and DC bias measurements for booster converter cores.

2 INTRODUCTION

This work unit was established with three initial objectives. The first objective for this effort was soft magnetic iron cobalt development for a potential rotor of a superconducting generator program. The small-scale iron cobalt work was successful and is described in Section 3.1 of this report. The second objective was to develop core-shell soft magnetic materials with high magnetization and high temperature capability. This work transitioned to tape core work and is described in Section 3.2 of the report. The third objective was to develop exchange-spring hard magnets, which could lead to an ultimate 2X increase in energy product compared to state-of-the-art permanent magnets. Exchange-spring magnet work is described in Section 2.2.

Besides the original objectives of the work unit, other areas were worked on as needed for collaborations, or for work on more basic magnetic material research, or for work on exchange-spring magnet precursor materials. The collaborative work included efforts on permanent magnet solenoids and converter core performance. This work is described in Sections 4.1 and 4.2 respectively. Basic magnetic material research focused on high-entropy magnetic alloys and phonon densities of states of magnetic alloys. This work is described in Section 3.3

Many papers were published by researchers and collaborators of this work unit. Only first authors directly involved with this work unit or major collaborators of this work unit are included in the Table 1.

Major breakthroughs that bring totally new magnetic systems to electrical power engineering are very hard and relatively rare. Perhaps just four breakthroughs in power magnetic materials have occurred since the 1930s. Ferrites were initially developed in Holland during the 1930s and 1940s [1]. Amorphous tapes or sheets for power transformers were developed by AlliedSignal during the 1970s [3]. Rare earth cobalt permanent magnets were first developed at the precursor to the Air Force Research Laboratory in the 1960s [1]. The first rare earth-iron-boron magnets were developed at the Naval Research Laboratory in the early 1980s [2].

If such breakthroughs do occur they typically transition to commercial success quickly due to the importance of magnetic materials to modern industrial economies. Besides such breakthroughs the design space of optimizing existing magnetic systems for specific applications is large. Additionally, even given a specific magnetic material, device design can be also be optimized. This work unit had efforts in all three of the research levels just discussed.

3 HARD (PERMANENT) MAGNETS

3.1 Rare Earth Magnets

Rare earth magnets made of a rare earth typically samarium or neodymium with cobalt or iron have the greatest energy products of any room temperature permanent magnets. The existing neodymium iron boron system and samarium cobalt system are of interest to research improved properties or as the hard magnetic component of exchange-spring magnets. In particular, samarium cobalt magnets and precursor powders or flakes were researched [4] [5] [6] [7]. Praseodymium rare earth magnets were also explored [8] [9].

The samarium cobalt research included both efforts on flake or powder preparation as well as efforts on bulk magnets. Flake and powder efforts involved various ball milling procedures on samarium cobalt. Flake thickness and its effect on performance were investigated [4]. Second quadrant curves were heavily affected by flake thickness as shown in Figure 1. In this work outstanding coercivity values up to 21 kOe were obtained for SmCo_5 flakes. Coercivity as a function of flake thickness is shown in Figure 2 [7].

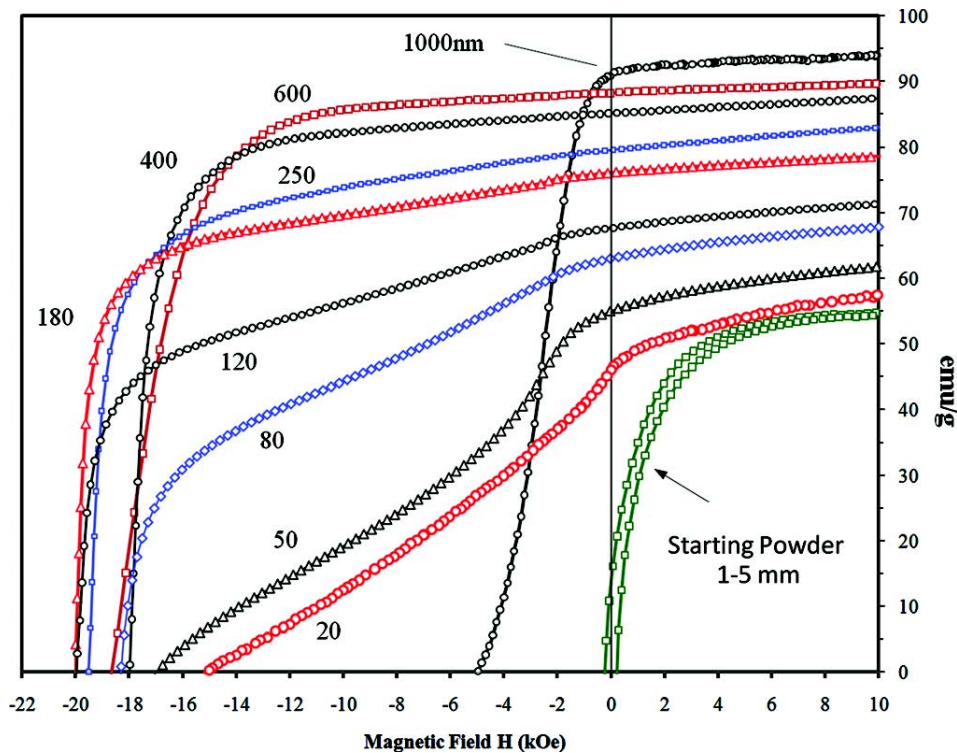

Figure 1. Demagnetization Curves vs. the Typical Flake Thickness

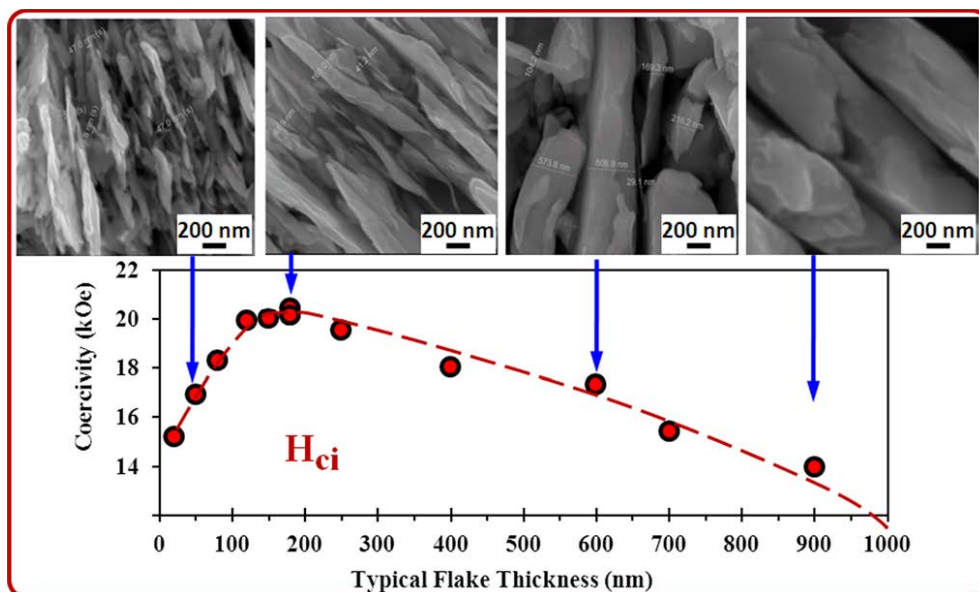

Figure 2. Intrinsic Coercivity vs. Typical Flake Thickness of SmCo_5

Much of the flake preparation was done by surfactant assisted ball milling. Studies were done on surfactants of varying molecular weights and on surfactant removal [5] [6]. Differential scanning calorimetry showed that surfactants of lower molecular weight were driven off of the samarium cobalt samples Figure 3.

Figure 3. Differential Scanning Calorimetry Curves for SmCo_5 Prepared with Different Surfactants

Praseodymium cobalt work also focused on surfactant assisted ball milling for flake production and consolidation experiments [8] [9]. Figure 4 shows the PrCo_5 nanoflakes with thicknesses around tens to hundreds of nanometers and widths of a few micrometers.

Figure 4. SEM Images of the Flakes Clumped at the Bottom of the Solvent

Some anisotropy was developed in these PrCo_5 flakes as shown in Figure 5 by comparing measurements of an oriented sample by vibrating sample magnetometer in parallel and perpendicular directions. However the hot-pressed bulk magnets lost coercivity due to oxidation.

Figure 5. Magnetization Curves of a PrCo_5 Powder Sample

3.2 Exchange-Spring Magnets

The general reasoning to consider a nanocomposite of hard and soft phases is that a large increase in energy product may be attainable [10]. The coercivity of the hard phase is combined with the high magnetization of the soft phase to make a theoretically stronger magnet as shown in Figure 6.

Figure 6. Nanocomposite Spring Exchange MH Loops

Five journal articles were published on exchange-spring magnets. Four of the journal articles were on samarium cobalt nanocomposites [11] [12] [13] [14]. The fifth article was on a $\text{LaCo}_5/\text{LaCo}_{13}$ nanocomposite [15]. Bulk $\text{Sm-Co}/\alpha\text{-Fe}$ nanocomposite magnets were made by high energy ball milling and subsequent quick hot-pressing. Soft phase amount and type were investigated. The effect of Fe soft phase content on the magnetic properties of the final bulk samples was examined. Increasing the Fe content significantly increased the saturation magnetization but at the cost of reduced coercivity (Figure 7). The optimum Fe addition for the highest maximum energy product was determined to be fifteen weight percent. Besides pure Fe a Fe-Co-V powder was also studied as a soft phase addition. The results indicated that Fe-Co-V powder was more readily alloyed with the Sm-Co phase during the milling procedure. This undesirable alloying was not as evident with Fe as the soft phase. For the final bulk magnets, nanoscale Fe particles existed in Sm-Co matrix with pure Fe addition, but with Fe-Co-V addition the soft phase particles were undetectable. Also, two methods for adding soft phase Fe into hard phase SmCo were utilized.

Figure 7. Demagnetization Curves of Bulk Sm-Co/ α -Fe Magnets with Different Amounts of Fe Addition and Maximum Energy Product vs. Fe Content

The investigation showed that milling Fe and SmCo together resulted in a more uniformly distributed mixture of nanoscale soft phase particles, improved squareness of the demagnetization curves of bulk nanocomposite magnets, and higher maximum energy product as compared to blending Fe with SmCo (Figure 8). Milling time also directly affected demagnetization curves (Figure 9).

Figure 8. Demagnetization Curves for SmCo Magnet and Sm-Co-Fe Composite Magnets Prepared from Blended and Milled Powder

Figure 9. Demagnetization Curves of Bulk Sm-Co/ α -(Fe,Co) Magnets as a Function of Milling Time

Substitution work also done with samarium cobalt based nanocomposites [14] [13]. Fluorine inclusion in alloys of $\text{Sm}(\text{Co,Fe})_z$ with $z > 8.5$, for nanocomposites of the 2:17 hard phase and Fe-Co soft phase were investigated. Partial hysteresis loops are shown Figure 10.

Figure 10. Partial Hysteresis Loops of $\text{Sm}(\text{Co}_{0.834}\text{Fe}_{0.166})_z$ with $z=6.5\text{--}14.7$

Figure 11 shows magnetic properties of the magnets as the soft phase increased in percent. Overall the inclusion of fluorine did not greatly improve magnetic performance as shown in Figure 12.

Figure 11. Magnetic Properties of $\text{Sm}(\text{Co}_{0.834}\text{Fe}_{0.166})_z$ vs. Effective z (28% soft phase for $z=13$ and 35% soft phase for $z=14.7$)

Figure 12. Effect of Fluorine Content on Magnetic Properties of $\text{Sm}[(\text{Co}_{0.7}\text{Fe}_{0.3})_{1-y}\text{F}_y]_{13}$ with $y = 0, 0.04$, and 0.08

Besides fluorine substitution, zirconium, niobium and copper substitutions were studied on samarium cobalt nanocomposite magnets [13]. Increasing zirconium content x from 0.02 to 0.05 led to significant refinement of the grain size in the melt-spun ribbons, from 80–150 to 20–50 nm as estimated by both XRD and SEM analyses. As a result of the formation of smaller grains, the coercivity and the maximum energy product were improved by 67% and 70% to 6.5 kOe and 9.5 MGOe, respectively, as seen in Figure 13.

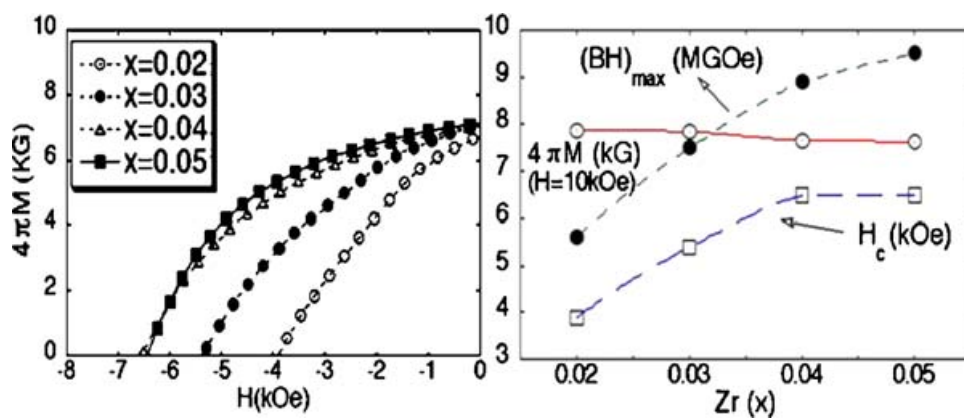

Figure 13. Demagnetization Curves and Magnetic Properties of Melt-spun $\text{Sm}(\text{Co}_{0.7}\text{Fe}_{0.3}\text{Zr}_x\text{B}_{0.04})_{10}$ Alloys with $x = 0.02$ to 0.05

Copper substitution enhanced coercivity of the magnets. Table 2 shows the compositions for the copper substitution studies. This substitution increased the squareness, H_k/H_c ratio, of the BH loops where H_c is the coercivity and H_k is the reversal field at 90% of the remanent magnetization (Figure 14).

Table 2. Compositions for Copper Substitution Studies

No.	Composition
1	$\text{Sm}(\text{Co}_{0.1}\text{Fe}_{0.3}\text{Zr}_{0.05}\text{B}_{0.04})_{10}$
2	$\text{Sm}(\text{Co}_{0.1}\text{Fe}_{0.3}\text{Zr}_{0.05}\text{B}_{0.04}\text{Cu}_{0.04})_{10}$
3	$\text{Sm}(\text{Co}_{0.1}\text{Fe}_{0.2}\text{Zr}_{0.05}\text{B}_{0.04})_8$
4	$\text{Sm}(\text{Co}_{0.1}\text{Fe}_{0.2}\text{Zr}_{0.05}\text{B}_{0.04}\text{Cu}_{0.04})_8$

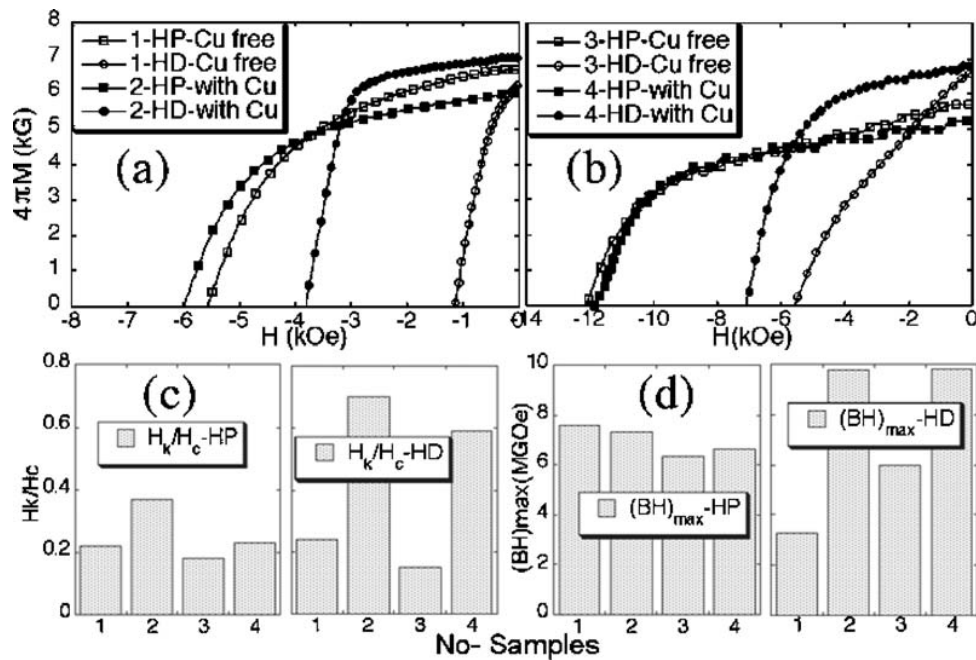

Figure 14. Demagnetization Curves (a) and (b), H_k/H_c ratio (c), and BH_{\max} (d) of Bulk Magnets Nos. 1 to 4 after Hot Pressing (HP) and Hot Deformation (HD)

When niobium replaced copper in a composition the grain size further reduced but the squareness and maximum energy product were reduced.

The lanthanum cobalt work explored the making of a nanocomposite of $\text{LaCo}_5/\text{LaCo}_{13}$ [15]. For this nanocomposite work, the LaCo_5 is the more coercive hard phase and the LaCo_{13} is the higher magnetization soft phase. As the soft fraction increased the magnet exhibited two-phase behavior, as seen in Figure 15. At 25 and 30% LaCo_7 , the magnets had a smooth demagnetization curve and a coercivity of over 15 kOe. Figure 15 also shows a strong

dependence on hot pressing temperature. This system shows promise as a permanent magnet system for high temperature applications.

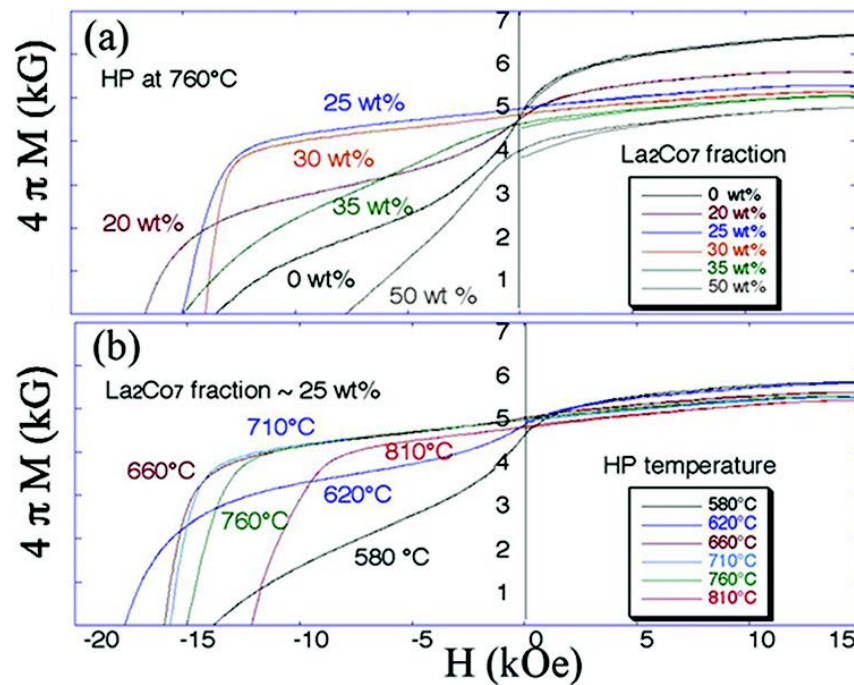

Figure 15. Demagnetization Curves of the Bulk La-Co Magnets

(Demagnetization curves are shown as (a) a function of La_2Co_7 weight fraction after hot pressing at 760 °C and (b) as a function of hot pressing temperature for 25 weight percent La_2Co_7 .)

4 SOFT (TEMPORARY) MAGNETS

4.1 Iron Cobalt Research

Iron cobalt alloys have the highest room temperature magnetization of any magnetic material. For this reason iron cobalt alloys are of interest to the aerospace industry where volume and weight are important. This work unit included research on iron cobalt alloys [16] [17]. The powder metallurgy processing of a gas atomized FeCoNbV alloy through hot isostatic pressing was studied. After hot isostatic pressing, the compacts were subjected to an ordering or disordering heat treatment in which the samples were heated up to 730 °C followed by a slow furnace cooling (ordered) or water quenching (disordered). Ball milling of the powder prior to hot isostatic pressing improved the yield strength by about 35%. Figure 16 shows the results for the four different processing conditions.

Table 3 shows the yield strength of two compositions as a function of oxidation time and temperature. For all samples the yield strength initially dropped with oxidation time and then the yield strength increased although the niobium containing samples did not surpass initial yield strength. The strengthening with aging time seems to be due precipitation reactions in the samples.

Figure 16. Yield Strengths of 750 °C Hot Isostatic Pressed Materials for Given Annealing and Ball Milling Conditions

Table 3. Yield Strength Values of FeCoV and FeCoVNb Alloys Measured at Room Temperature and 482 °C as a Function of Oxidation Time

Time (hours)	FeCo-2V		FeCo2V-0.3Nb	
	Yield Strength	Yield Strength	Yield Strength	Yield Strength
	Room T (MPa)	482 C (MPa)	Room T (MPa)	482 C (MPa)
0	417	410	545	484
100	403	363	489	450
1000	426	401	479	416
2000	427	351	374	352
5000	524	460	390	379

4.2 Tape Core Research

Soft magnetic research includes both research into tape core materials and research involving inductor applications. The tape core research involves both amorphous or nanocrystalline materials [18] [19]. This work studied the properties and nanocrystallization characteristics of HITPERM based $\text{Fe}_{68.8}\text{Co}_{17.2}\text{Hf}_7\text{Cu}_1\text{B}_6$ and $\text{Fe}_{69.6}\text{Co}_{17.4}\text{Hf}_7\text{B}_6$ alloys. The alloys only differed in containing copper. These alloys were prepared by arc melting and then melt spinning at a wheel speed of 35 m/s. The presence of copper had no effect on the grain size of the alloys. Their respective magnetization curves as a function of increasing temperature are shown in Figure 17.

Figure 17. Thermomagnetic M(T) Plots of $\text{Fe}_{68.8}\text{Co}_{17.2}\text{Hf}_7\text{Cu}_1\text{B}_6$ and $\text{Fe}_{69.6}\text{Co}_{17.4}\text{Hf}_7\text{B}_6$ Alloys Measured under an Applied Field of 1 kOe

These samples first go through their amorphous Curie temperature which drops the magnetization and then after crystallization a second drop occurs due to a phase change from bcc

to fcc. The crystallization temperature of the copper containing alloy was higher at 808 K then the copper free alloy at 770 K. Overall, the addition of copper has no effect on final grain size, but it increases coercivity and lowers saturation magnetization and permeability.

In another study nanocrystalline iron cobalt based alloys with Hf or Ta or both were investigated for high frequency applications. Magnetization and calorimetry plots are shown in Figure 18. Amorphous alloys of $(\text{Fe}_{81}\text{Co}_{19})_{84}\text{M}_9\text{B}_7$ where $\text{M} = (\text{Hf}, \text{Ta}, \text{ or HfTa})$ were prepared by meltspinning. The alloys were then annealed for increasing times at their respective crystallization temperatures. Overall, the nanocrystalline alloys had coercivities less than 0.4 Oe and saturation inductions greater than 1 Tesla. The electrical resistivities of the amorphous ribbons were all similar with values of $\sim 180 \text{ Ohm-cm}$. After annealing at the crystallization temperature, the $\text{M} = \text{Ta}$ alloy had the largest resistivity of 140 Ohm-cm. The Ta alloy also had the best high frequency properties, with an initial permeability of 822 at 1 MHz. Figure 19 shows the complex permeability of the Ta alloy as a function of frequency.

Figure 18. Magnetization as a Function of Temperature from Vibrating Sample Magnetometry and Results from Differential Scanning Calorimetry

Figure 19. Initial AC Permeabilities as a Function of Frequency for the FeCoTaB Sample Annealed at $T_{x1} = 551.8\text{C}$ for increasing anneal times

4.3 Basic Science of Soft Magnetic Materials

The basic science of soft magnetic materials included research on phonon density of states of magnetic alloys, high-entropy magnetic alloys and magnetocaloric alloys. Most of these studies involved measurements at Department of Energy National Laboratories. X-ray scattering measurements were performed at Argonne National Laboratory and neutron scattering measurements were performed at Oak Ridge National Laboratory.

The high-entropy alloys studies all involved alloys containing iron and usually nickel, chromium and cobalt [20] [21] [22]. These materials were studied as candidates for magnetic or magnetocaloric use. High-entropy alloys have nearly equal atomic fractions of each of their component elements. These materials have been studied for their high mechanical and chemical properties such in hardness, wear resistance, and corrosion resistance. Long-range chemical ordering, magnetic and vibrational properties, and magnetic entropy were investigated on these alloys. Figure 20 shows a vibrational density of state result for an equimolar FeCoCrNi alloy. This fcc FeCoCrNi alloy was given a heat treatment at $480\text{ }^{\circ}\text{C}$ for two weeks and then slow cooled to room temperature. Comparing the phonon density of states from neutron scattering measurements to a study on the Fe-atom vibrational modes suggests that there is no evidence of long-range chemical ordering.

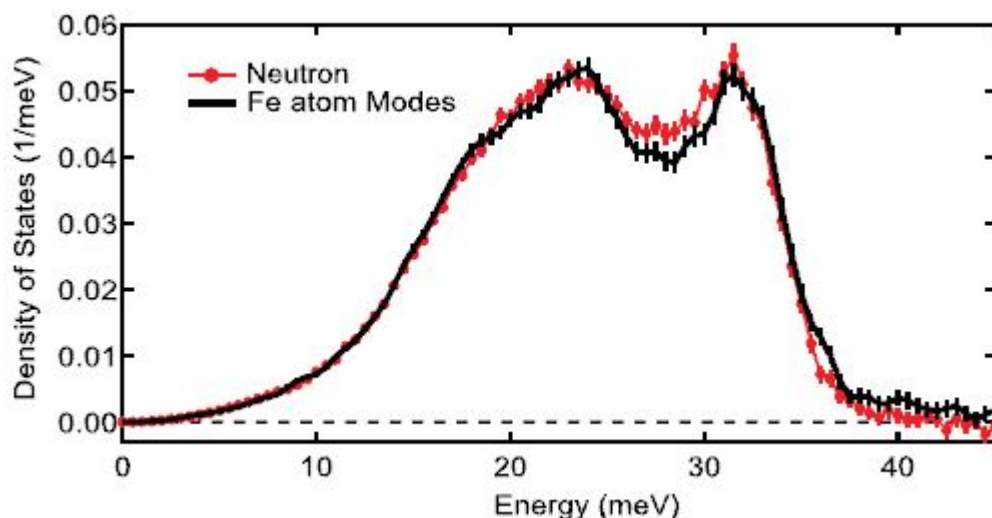

Figure 20. Vibrational Density of States for FeCoCrNi from Inelastic Scattering of Neutrons and X-rays

Binary alloys such as Fe-Co, Ni-Fe and Fe-V were also studied [23] [24] [25] [26]. The Fe-Co system is magnetically important due to its high Curie temperature, high magnetization and high permeability. These alloys may be disordered or ordered. Ordered Fe-Co alloys tend to be brittle and are less useful for engineering applications. The disordered phase can be obtained by quenching from the high temperature disordered phase. Figure 21 shows the small but observable change of phonon energy due to order. The ordered alloy has on average stiffer bonds due to more unlike bonds compared to the disordered alloy.

Figure 21. Phonon Density of State Curves for Disordered and Ordered Fe_{0.50}Co_{0.50} Alloys

The bcc phase of the iron-vanadium alloy system spans the full composition range. Phonon density of states as composition varies is shown in Figure 22. Changes in magnetic properties with composition make these alloys interesting to study the effects of magnetism on phonon thermodynamics.

Figure 22. Phonon Density of State Curves for Fe, V and Fe-V Alloys
(The alloys are at 300 K, corrected for neutron weighting and with curves offset by integer multiples of 0.04 meV⁻¹.)

5 APPLICATIONS AND MODELING

5.1 Permanent Magnet Solenoids

One major application addressed in this research effort was the modeling and building of a large bore permanent magnet solenoid [27] [28]. The center magnetic field needed to be very uniform for this application. Figure 23 shows the overall design with a section cut out for clarity. Modeling was performed using ANSYS Maxwell. One caveat in particular for the modeling of the field for the solenoid was the role of surrounding air region or padding space (Figure 24). If the air region was too small the field accuracy was increasingly incorrect as shown in Figure 25. Figure 26 shows the uniformity of the magnetic field at the center axial position and at a position 50 mm from center. The modeled versus measured magnetic field agree to within 5%. The completed magnet assembly is shown in Figure 27.

5.2 Cores for Converters

Cores were investigated for use in DC-DC boost converters. This work was done in collaboration with AFRL/RQQE. In the first study three types of coupled inductors were investigated for performance [29]. The test circuit for this work is shown in Figure 28. Three types of ferrite cores were made (Figure 29). Efficiency data of the cores is given in Table 4. Pickup coil locations are shown in Figure 30. The square core with the forty-five degree gaps had the best performance as given in Table 5. The field distributions for the square 45° gap core inductor were also more uniform throughout the core than the other two inductor types (Table 5).

Figure 29. Winding Configuration of the Coupled Inductors
(L to R: E-E core, square 45° gap core, and square 90° gap core.)

Table 4. Boost Converter Efficiency Data

Inductor type	Vin (V)	Iin (A)	Vout (V)	Pout (A)	Pout (W)	Converter efficiency (%)
E-E core	60.0	27.57	158.7	9.69	1538	93.0
Square 90° gap	60.0	27.44	158.8	9.64	1531	93.0
Square 45° gap	60.0	27.20	158.8	9.79	1555	95.2

Figure 30. Pickup Coil Location for the Coupled Inductors

Table 5. Calculated and Simulated AC Flux

Inductor Type	Y1 (μWb)	Y2 (μWb)	Y3 (μWb)	G1 (μWb)	G2 (μWb)	G3 (μWb)
E-E core	1.76	2.07	0.84	1.45	1.58	0.69
Simulation (E-E)	1.36	1.85	0.90	1.24	1.32	0.64
Square (45° gap)	1.65	1.96	1.67	1.30	1.42	1.28
Simulation (45° gap)	1.84	2.10	1.83	1.75	1.85	1.75
Square (90° gap)	1.58	1.65	1.28	1.20	1.23	1.00
Simulation (90° gap)	1.80	2.10	1.86	1.69	1.85	1.75

Note: For 1 amp through the coil on which the pickup coils are placed.

In the second study loss mechanisms were studied with a DC bias [30]. Inductors or transformer cores in electronic systems are often subjected to DC bias-flux conditions. These DC bias conditions can result in distorted hysteresis loops and increased core losses. The wound core for this study is shown in Figure 31. The test circuit is shown in Figure 32. This study found that Steinmetz equation for loss underestimated losses under DC bias Figure 33. The Steinmetz equation is

$$P = Af^{\alpha}B^{\beta} \quad (1)$$

where P is power loss (W/kg), A is the fitting coefficient, f is the frequency (kHz) and B is the flux density (Tesla) and α and β are fitted exponential factors. A pre-magnetization field increases core losses as shown in Figure 34. These losses are a design consideration especially for cores operated at greater than 100 kHz.

6 CONCLUSIONS

Progress was made in several areas of magnetic materials and applications. Rare-earth powder and flake research has been promising with the production of materials with outstanding coercivities. Exchange-spring magnet research has produced smoothly coupled nanocomposite magnets, but energy products do not exceed existing rare-earth based magnets. Tape core material development has been promising but scale up issues remain.

Application successes include the modeling, fabrication, testing and patenting of a permanent magnet solenoid. Inductor DC-bias and loss characterizations also proved noteworthy.

7 RECOMMENDATIONS

The development of new magnetic materials and applications is an on-going quest for research groups around the world. With the importance of magnetic materials, new superior and cost-effective magnetic materials would have an easy transition into commercial and defense sectors.

The assumptions in the original exchange-spring paper by Kneller and Hawig should be revisited since research groups around the world have not yet produced greater energy products than existing neodymium rare-earth iron boron magnets.

Higher operating temperatures with high energy products should be researched. Optimization of tape cores for higher frequencies should also be pursued. Collaborative efforts throughout AFRL should be developed as needed. The optimization of magnetic devices for applications including converter and pulse power systems should be worked on. Electromachine research could be developed beyond just the current modeling efforts to include hardware demonstrations.
