Development of Quiet-Flow Supersonic Wind Tunnels for Laminar-Turbulent Transition Research: Final Report for NASA Langley Grant NAG-1-1133

Steven P. Schneider
Assistant Professor of Aerodynamics
School of Aeronautical and Astronautical Engineering
Purdue University
West Lafayette, IN 47907-1282

#### Abstract

This grant supported research into quiet-flow supersonic wind-tunnels, between May 1990 and December 1994. Quiet-flow nozzles operate with laminar nozzle-wall boundary layers, in order to provide low-disturbance flow for studies of laminar-turbulent transition under conditions comparable to flight. Major accomplishments include: (1) the design, fabrication, and performance-evaluation of a new kind of quiet tunnel, a quiet-flow Ludwieg tube; (2) the integration of pre-existing codes for nozzle design, 2D boundary-layer computation, and transition-estimation into a single user-friendly package for quiet-nozzle design; and (3) the design and preliminary evaluation of supersonic nozzles with square cross-section, as an alternative to conventional quiet-flow nozzles. After a brief summary of (1), a description of (2) is presented. Published work describing (3) is then summarized. The report concludes with a description of recent results for the Tollmien-Schlichting and Görtler instability in one of the square nozzles previously analyzed.

## 1 The Purdue Quiet-Flow Ludwieg Tube

A quiet-flow Ludwieg tube has been designed, constructed, and tested at Purdue over the past 5 years. This is the first low-cost quiet-flow facility constructed with a design that has the potential to reach substantial quiet Reynolds numbers and test-section sizes. It is also the first quiet-flow facility with good optical access (except for the defunct JPL tunnel [9] and the small MSU facility [7]). The facility

is currently in operation with a 3.8 by 4.3 inch Mach 4 test section that is quiet to a length Reynolds number that exceeds 400,000. This Reynolds number already allows testing of receptivity and roughness effects. More importantly, the way is now open to development of substantially higher Reynolds number facilities with short run-times, at low costs. Current plans call for the installation in the Purdue Ludwieg tube of the obsolete first-generation nozzle blocks for the NASA Langley Mach 3.5 pilot tunnel. These blocks, which have a 6 by 10 inch exit, should allow achieving a quiet length Reynolds number of 2.7 million at 30 psia stagnation pressure, according to reference [4].

The design and construction of the facility is documented in references [13], [15], and [16]. The test results were presented in reference [17], and have been accepted for journal publication [14]. More recent results were presented in reference [19].

# 2 Integrated Software for Design of 2D and Axisymmetric Quiet-Flow Supersonic Wind Tunnel Nozzles

At the commencement of this effort, it was expected that a new nozzle would have to be designed and constructed for the Purdue Ludwieg tube. Although this has not yet been required after all, considerable effort has been expended in developing an integrated, easy to use quiet-nozzle design system from the several separate codes that were originally in use for this purpose at Langley. The following section briefly describes and documents this relatively user-friendly quiet-nozzle design software.

#### 2.1 Method-of-Characteristics Nozzle-Design Code

The state of the art in the design of supersonic wind tunnel nozzles involves the use of 2D or axisymmetric method-of-characteristics (MOC) codes for determining the nozzle shapes that result in uniform exit flow. A good introductory description of the basic problems is presented in sections 15-5 and 16-4 of reference [23]. Although fully three-dimensional MOC codes exist, they would have to be iterated in order to produce uniform flow at the nozzle exit, a basic requirement for wind tunnel nozzles [12]. Thus, consideration is here restricted to flows derivable from 2D or axisymmetric MOC solutions.

The Sivells wind-tunnel nozzle design code was selected for use in 1990. Unlike the custom-modified code used by Chen for the Langley nozzle designs [21], it is fairly well documented in reference [20], and the source code is available. Although it is old FORTRAN-IV code, it is possible to follow much of the logic from the

code itself. In addition, the Sivells code is capable of generating nozzles with the radial-flow regions that are advantageous from a Görtler stability viewpoint [5].

The manual for the code devotes 8 pages to the description of the input deck, which allows for many different combinations of nozzle geometries. To simplify the use of the code, a FORTRAN program was written to automatically generate the input deck from the answers to a few simple questions that are answered interactively. This program, SIVINPUT, which is appended, sets most of the parameters in the code. The internal documentation contained in SIVINPUT in the form of comments will have to suffice for documentation at the present time.

Numerous modifications have been made to the Sivells code over the past 4 years, although most of these are fairly minor. The mainframe-style input/output structure was modified to a friendlier form, in which the input and output files are automatically generated by adding 3 character suffixes to a user-supplied 8 character rootname. If the rootname is here called username, then SIVINPUT generates username.inp which is then read by SIVELLS. A subroutine (WRTOBL; see appendix) was added to write selected output in a form suitable for ready translation into Harris code input (file username.bl). The WRTOBL subroutine also writes data for the conditions along the centerline of the sidewalls to the file username.cl, and integrates the tracks of mach lines originating on the sidewall, for determining the width of quiet-flow regions in 2D nozzles. The WRTOBL subroutine also writes out the derivatives of the wall contour, as generated in the MOC algorithm, in order to obtain accurate values of the local wall curvature for Görtler computations. Finally, WRTOBL was also modified to call the Hopkins-Hill subroutines developed and documented in reference [2], in order to determine the shape of the bleed slot lip upstream of the throat. Although this means that a different algorithm is used to determine the transonic throat shape upstream and downstream of the throat, the two algorithms seem to merge smoothly and accurately into one another. This agreement is not surprising, since both the upstream and downstream transonic flow algorithms are based on near-sonic perturbation theory, so they must agree very well near the throat where the sound speed is nearly sonic, at least for large radius of curvature wind-tunnel-type throats. Error trapping code was inserted to address problems with user-friendliness, when these were encountered. The common block references were made consistent to reduce compiler difficulties. The array sizes allowed by the code were also increased, to improve accuracy. Minor changes were also made to SIVELLS to allow restructuring it to structured Fortran-77 using the commercial software package FOR-STRUCT (Cobalt Blue, Inc., Roswell, Ga.).

The only significant change to the Sivells internal algorithm was made when it was determined that the code would not generate internal streamlines downstream of the radial flow region, for the nozzle shapes desired (the original code will only generate internal streamlines for the special case where ETAD = 60.) This bug was

fixed by duplicating lines 111 and 112 of the AXIAL subroutine above line 43 in AXIAL.

Since a nozzle with 10 internal streamlines for square nozzle designs can be generated on a 66MHz 486-class PC in less than 3 minutes, the system is very practical for design work.

#### 2.2 Sivells to Harris Interface Code

The program MAKEBLIN was written to take the output file from the Sivells code, username.bl, and generate an input file for the Harris code, username.bli. The Reynolds number scaling information required is read in from the auxiliary file username.re, which contains the throat radius, total pressure and temperature, and so on, and must be hand-generated. It uses various defaults to generate a complete input deck for the Harris code, including the streamwise grid-point locations. It is also capable of generating Harris code input for other inviscid-flow generators. The code is heavily commented, as can be seen from the listing in the appendix. The highly automatic generation of the complex input files required for the Harris code make design studies relatively easy to carry out. This code runs in seconds on the 66MHz PC.

#### 2.3 Harris Boundary-Layer Code

The Harris boundary-layer code is documented with a good user's manual [8] and is written in structured Fortran. It is a good and standard finite difference code with which to compute 2D and axisymmetric boundary layers. For quiet-nozzle work, the boundary layers are assumed to be laminar (since the nozzle-wall boundary layer is only of interest up to the point where it becomes transitional). Thus, the turbulence model incorporated in the code is not an issue.

Again, minor modifications were made to this code, to ease input/output. The input/output files are again automatically generated by appending suffixes to the user-supplied rootname (e.g., username). The input data is read from username.bli, and the standard output is written to the file username.blo. In addition, the surface conditions written using IPRT commands are written in tabular form to username.prt, and the profiles written using IPRO commands are written in tabular form to username.pro. This allows rapid plotting of selected surface conditions, and eases translation of the output into a form suitable for the transition-estimation code. In particular, selected derivatives of profile quantities are written to username.pro, as generated in the program, so that they can be passed to the transition-estimation program with greater accuracy. Error-trapping code was also added, as needed to

ease use. The modified code has been used in required undergraduate course projects with good success.

This code also runs in a few minutes on the 66 MHz PC, so again the system is convenient for design purposes.

#### 2.4 Harris to e\*\*MALIK Translation Code

The program BLTOSTAB was written to take the output of the Harris code and translate it into the binary file form used by the e\*\*MALIK code. This relatively long code generates the sophisticated binary input file, username.bfl, required by the stability code e\*\*MALIK. It does this by reading the Harris code output files, username.prt and username.pro, along with the wall-curvature data saved in username.bl from the Sivells code, and the Reynolds number scaling data saved in username.re. Besides the main binary output file, BLTOSTAB generates username.cur for checking the surface curvature computations, username.gor for printing Görtler number data, and username.sck for printing information to check the computations for Sivells input data. BLTOSTAB can also read in surface geometry data that is then differentiated numerically to determine radii of curvature; this feature was implemented to allow running the Chen test case for Görtler instability, described below. In this case, the file username.usk is generated for checking computations performed using data not obtained from the Sivells code. A listing of BLTOSTAB is appended. For lack of resources, this heavily commented listing must suffice for documentation.

#### 2.5 Transition-Estimation Code

The Langley program e\*\*MALIK was used to perform e\*\*N estimates of transition location [11, 10]. Although the manual, reference [11], is old and imprecise, it is apparently the best version in existence. The manual has been supplemented by examination of the source code, and private communications with Mujeeb Malik, Robert Spall, and Scott Anders. Because of the uncertainties of using this complex code with limited documentation, test cases were run for both the T-S and Görtler instabilities, to confirm proper operation.

The e\*\*MALIK code was also modified slightly, again only to change the input/output formatting somewhat, and to add error trapping code. The code reads stability computation instructions from a file piped into the executable with the Unix < command, and writes the general output to a file specified with the Unix > command. It writes summary data to a file username.sum; the string username is passed to the code through an additional read statement at the bottom of the input file. The binary-form input data for the boundary-layer profiles is read from

username.bf1. The code was also modified to automatically loop through several different frequencies or spanwise wavenumbers in one execution, a property the version furnished to this author in 1991 did not have, although the manual suggested that it did. This is the most CPU-intensive code in this quiet-nozzle design system. The author has most recently been executing it on his department server, a 4-CPU Sun Sparcstation 1000 that has 256 megabytes of RAM. A half-dozen different frequencies can be studied over few dozen streamwise stations in typical runs that can usually be carried out overnight. Thus, although this code is CPU-intensive, it remains practical to perform design studies with it in a modern workstation environment.

#### 2.5.1 Test Case for T-S Instability Computations

Use of the e\*\*MALIK code for computation of T-S instabilities was benchmarked back in the summer of 1990, using test case 6 from reference [10]. Test case 6 is for the flow on a flat plate at Mach 4.5,  $R = \sqrt{U_e x/\nu_e} = 1500$ , adiabatic wall, and a total temperature of 1100 Rankine. Table IX on p. 407 of reference [10] gives spatial case results for a nondimensional frequency  $\omega = 0.23$ . There, the eigenvalue  $\alpha$ is given as (0.2534081, -0.0024932) for the most accurate computation. The author's version of e\*\*MALIK was first checked by running it with the internal self-similar boundary-layer solver, which produced (0.253397, -0.00250489). This agreement was considered to be very good. However, when the self-similar boundary-layer profiles were generated by the author of this paper, translated into e\*\*MALIK input form by BLTOSTAB, and the stability was recomputed, the results were not as good. In this case, at a slightly different R = 1495,  $\alpha$  was found to be (0.25195, -0.00229). This 10 percent difference was doubtless caused by imprecise generation of the boundarylayer profiles; the overall agreement indicates that the BLTOSTAB code generates the proper e\*\*MALIK input. At the time of this test, the BLTOSTAB code differentiated the Harris velocity profiles numerically, instead of using the internally-generated Harris derivatives, so agreement would no doubt be better at the present time.

#### 2.5.2 Test Case for Görtler Instability Computations

Benchmark data for the Görtler test-case was generously supplied by Frank Chen, along with data for the nozzle coordinates and pressure distribution. The data is for the Mach 6 NTC nozzle currently in use at Langley [6], at a total pressure of 100 psia and a total temperature of 360F, under adiabatic wall conditions. The summary output file printed by the e\*\*MALIK code was supplied, although detailed data on the boundary-layer computations performed by Chen were no longer available. This test-case tests both the boundary-layer computations (carried out in both cases

with the Harris code) and the use of the e\*\*MALIK code. Since the Chen nozzle design uses a modified Nelms code, and the system described here uses the Sivells code, the MOC nozzle-design code itself is not tested. Since the Chen data for the surface coordinates are given to four places, without derivatives, auxiliary code was added to the BLTOSTAB routine to allow reading in this non-Sivells coordinate data. The Chen coordinate data was differentiated using the same LaRC routine used by Chen, CSDS, which was obtained from LaRC computing center personnel.

Figure 1 shows the radius of curvature, R, as a function of the axial location z, which is zero at the throat. Note that z is the coordinate along the centerline of the tunnel, not the arclength s along the nozzle wall. Smooth distributions are obtained in the concave region downstream of about z=8 inches, but the distributions become noisy near the downstream end of the nozzle. Additional smoothing in the differentiation might have reduced this effect. The precise curvature distributions computed by Chen were unavailable. The Harris code was run using 870

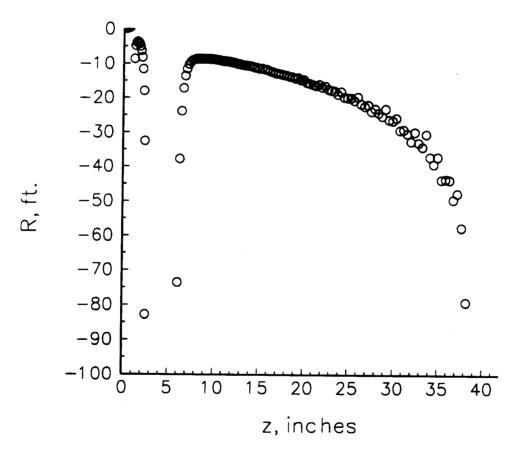

Figure 1: Radius of Curvature for Mach 6 Test Case

streamwise stations and 51 points in the wall-normal direction. Figure 2 shows the edge Mach numbers,  $M_e$ , interpolated by the Harris code to the Chen-supplied data. The limited precision of the data supplied causes the Harris code to generate some

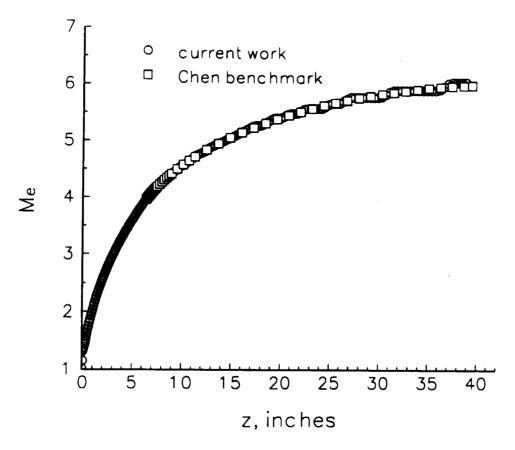

Figure 2: Comparison of Edge Mach Number for Mach 6 Test Case

waviness while interpolating. Figure 3 shows the boundary-layer momentum thickness,  $Re_{\theta}$ , comparison. The waviness in the  $M_{e}$  interpolation clearly causes some waviness in the momentum thickness Reynolds number,  $Re_{\theta}$ , and the current results are somewhat above those used by Chen. The cause of the small difference is difficult to determine, since the details of the Chen computation are no longer available. Both the wall radius of curvature and the momentum thickness are reflected in the Görtler number computations, presented in Figure 4. Here, the Görtler number  $G_{\theta}$  is based on the momentum thickness  $\theta$ . Overall, the agreement is good, although the interpolations and differentiations required in the re-analysis of the Chen data clearly cause additional scatter. No smoothing has been applied to these computations. Finally, Figure 5 shows the results of the N-factor computations carried out

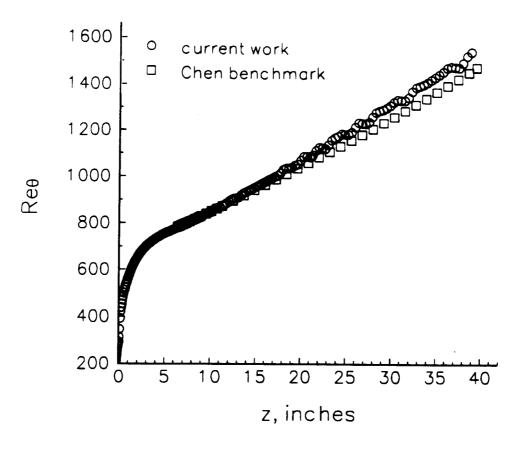

Figure 3: Comparison of Reg for Mach 6 Test Case

using the e\*\*MALIK code, for the case with 125 waves around the circumference of the nozzle, which is nearly the most amplified case. Here, s is the arclength along the nozzle wall, with s=0 being located at the throat. Clearly, the operation of the Harris, BLTOSTAB, and e\*\*MALIK codes is fundamentally correct, for the results agree well. Although the close agreement is clearly in some part fortuitous, given the minor disagreements in the previous plots, the test-case shows that this part of the integrated and fairly automatic software produces the proper results.

## 2.6 Summary of Software Status

This software is now working and fairly well tested. With this semi-automatic software, it is possible to generate nozzle designs in seconds for 2D and axisymmetric nozzles, although square nozzles take longer. The boundary layers on 2D and axisymmetric nozzles can be computed in minutes on a PC, and then a few overnight computations on a modern workstation can be performed to estimate the location

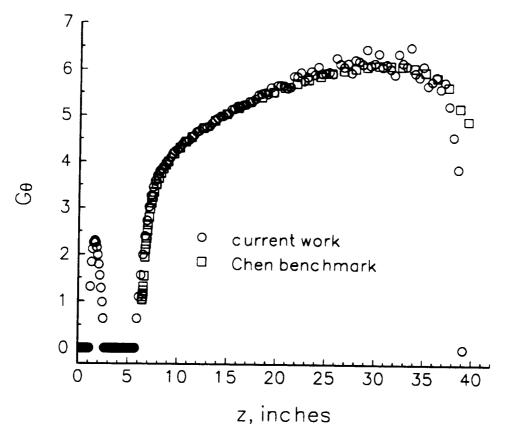

Figure 4: Comparison of  $G_{\theta}$  for Mach 6 Test Case

of transition. Thus, one complete iteration of a quiet nozzle design can be carried out in a workstation environment in a few days, using only an hour or two per day of engineering labor.

# 3 Design and Preliminary Evaluation of Supersonic Wind Tunnel Nozzles with Square Cross Sections, for Use in Quiet-Flow Facilities

#### 3.1 Introduction

This effort began in September 1992, and continued intermittently until the termination of the grant. Sivell's code was again used for the method-of-characteristics (MOC) design of the nozzles [20]. Although reference [20] suggests that the code

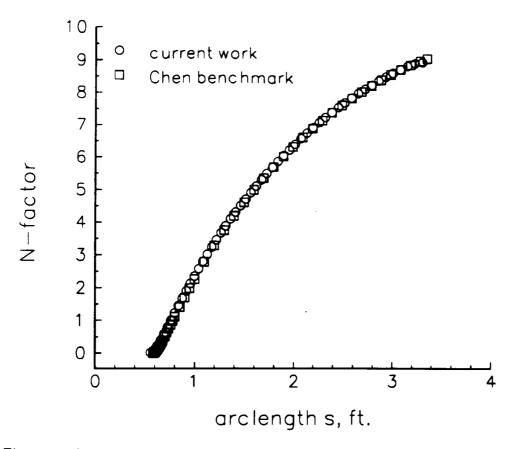

Figure 5: Comparison of Görtler N-factors for Mach 6 Test Case

will generate internal flow streamlines for all the types of nozzles which the code can generate, minor modifications proved to be necessary in order to generate internal streamlines for nozzles that included radial-flow regions. A post-processing code was then written to trace the streamlines upstream from a square cross-section drawn in the nozzle-exit plane, in order to generate near-square cross-sections from the exact MOC results, between the exit and the throat. This post-processing code was completed in fall 1992 and documented in reference [18]. The Hopkins-Hill technique for designing the transonic region of the nozzles (up to the bleed slot lip) still needed to be implemented in a reasonably convenient way. This work was completed during early summer 1993 and documented in reference [2]. Graduate student Timothy Alcenius carried out the Hopkins-Hill work, and then performed 3D Navier-Stokes computations of the mean flow in the square nozzles. The position of transition due to the crossflow instability was estimated using these computations and the crossflow Reynolds number technique. Most of the Navier-Stokes results are available in

flow Reynolds number technique. Most of the Navier-Stokes results are available in reference [1], which appeared in June 1994. Complete results are available in reference [3], which will be appended to the final report for NAG-1-1607. A summary of the results has been submitted for publication in the AIAA Journal of Aircraft.

Although the above analyses suggested that crossflow instability would be the dominant factor in transition of the boundary layers on the square nozzle walls, computations of the Tollmien-Schlichting instability and the Görtler instability were also carried out using the e\*\*MALIK code [10]. Although the actual nozzle-wall boundary layer is three-dimensional, these computations were carried out using the results of a 2D boundary-layer computation of the sidewall boundary layer in the symmetry plane. Analyses were only carried out for the long Mach 2.4 nozzle described in [1], since this was thought to be the worst case for these instability modes, and since the short Mach 2.4 nozzle appeared less practical from the standpoint of the crossflow instability. A detailed description of these computations forms the remainder of this section.

## 3.2 Computations of the Centerplane Boundary Layer in the Long Mach 2.4 Square Nozzle

The coordinates of the long Mach 2.4 nozzle analyzed by Alcenius are given on p. 129 of the appendix of reference [3]. These coordinates were obtained by Alcenius using SIVINPUT and the Sivells design program [20]. The input parameters are specified on p. 23 of reference [3] (Nozzle 2 of Table 1). It should be noted that the nozzle design codes produce a nozzle with a bleed slot lip that protrudes far upstream of the throat. Alcenius then cut off the upstream extent of the bleed slot, according to specifications provided by Ivan Beckwith from NASA Langley, in order to produce a bleed slot originating 0.175 meters (0.574 ft.) upstream of the throat (p. 129 of reference [3]). For the computations presented here, the bleed slot was cut off 0.612 ft. upstream of the throat; interpolation to the exact position used by Alcenius was not performed. Figure 6 shows that the coordinates are identical, except for the difference in leading and trailing extent (Alcenius's last point is at 4.197 ft., the last point used here is 4.165 ft.). Here, z is again the coordinate along the nozzle centerline, beginning at the throat, and the y-axis is normal to the z-axis. Figure 7 shows the displacement thickness  $(\delta^*)$  of the 2D boundary layer calculated using the centerplane pressure distribution and the Harris code [8]; the close agreement shows that the methods used were the same. Although the small discrepancy about 3 ft. downstream of the throat is somewhat troubling, this slight variation in a strong favorable pressure gradient should not have much effect on the stability. Although the point is not discussed in reference [3], it should be noted that both computations

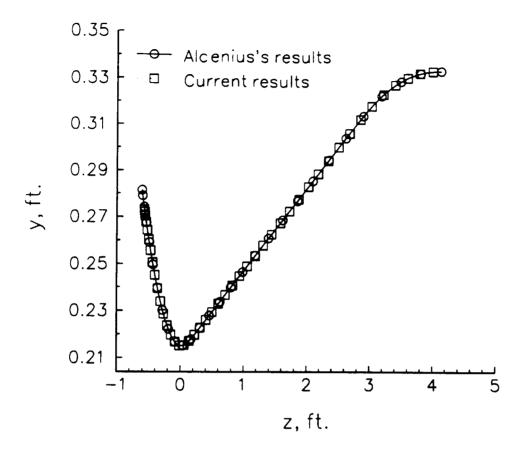

Figure 6: Coordinates of Long Mach 2.4 Square Nozzle

computations. Also, both computations presented here were carried out assuming an isothermal wall temperature of 520 Rankine. Since this is nearly equal to the stagnation temperature, 540 R, and the Mach number is not high, the conditions are nearly adiabatic. The stagnation pressure is taken as 100 psia, as in Alcenius's work.

# 3.3 Estimates of Transition in the Long Mach 2.4 Square Nozzle due to the Görtler Instability

This instability was analyzed with the e\*\*MALIK code, using the nozzle-design software described above. The boundary-layer data were read in through the external binary file generated from the Harris code output by the translation program BLTOSTAB. The body was assumed 2D, 71 grid points were used in global computations and 141 in local computations, and computations were begun at the location

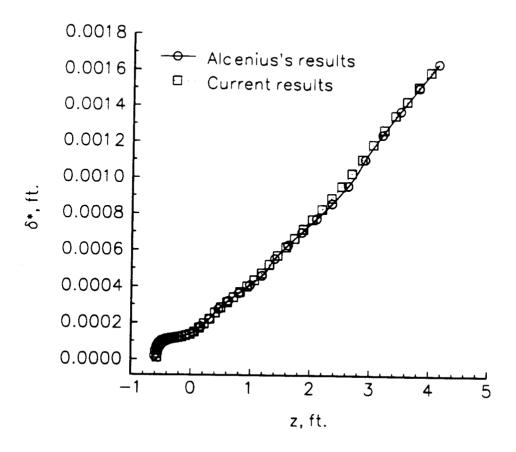

Figure 7: Comparison of Centerplane  $\delta^*$  Values for Long Mach 2.4 Square Nozzle

where the curvature becomes concave. Since ibeta was set to 0, the input parameter betx is actually the dimensional wavenumber, k, per ft. (note that the e\*\*MALIK manual [11] is erroneous in this regard; the correction was provided verbally by M. Malik on 16 July 1991). This wavenumber parameter was varied through 500, 1000, 1200, 1400, 1600, 1800, 2000, 2200, 2400, 2600, 2800, 3000, and 4000 per ft. Since the momentum thickness  $\theta$  of the boundary layer at the first concave station was about  $2 \times 10^{-4}$  ft., and the wavelength  $\lambda = 2\pi/k$ , this corresponds to spanwise wavelengths  $\lambda/\theta$  ranging from 60 to 8. The corresponding values of BETA output by the code range from 0.19 to 1.9; these spanwise wavenumber values are non-dimensionalized by the distance from the leading edge and the edge values of the fluid properties. The spanwise wavelength of the Görtler waves is maintained constant as the amplification is integrated downstream. Figure 8 summarizes the integrated amplification between the streamwise distances of 2.80 and 4.17 ft. The peak amplification is about 5.7, which occurs at a BETA of 0.9. Based on the Langley

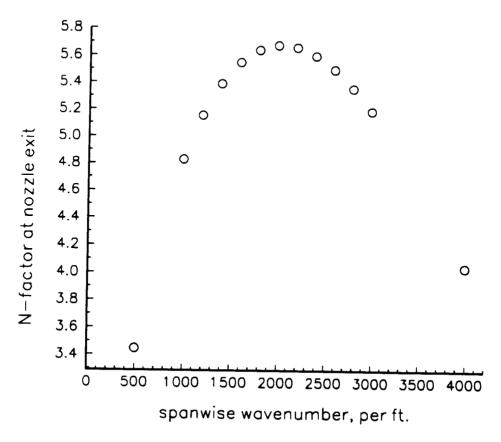

Figure 8: Görtler N-factors at Exit of Long Mach 2.4 Square Nozzle

N-factor criterion of 7.5 for Görtler transition [22], this instability is not expected to cause transition. Of course, this estimate neglects interactions with roughness or other instabilities.

# 3.4 Estimates of Transition due to the T-S Instability

The T-S computations were performed with the e\*\*MALIK code, and with the same boundary-layer profiles used for the Görtler computations. Many computations had to be performed in order to find the unstable range of frequencies. The results are shown in Figure 9. Frequencies in the neighborhood of 6 kHz are most unstable. These have a wave-angle PSI of about 67 degrees, which appears to be reasonable. The nondimensional frequency OMEGA is about 0.009 for these waves. Since the integrated N-factor is less than 2, it appears unlikely that T-S instability would contribute substantially to transition in this nozzle.

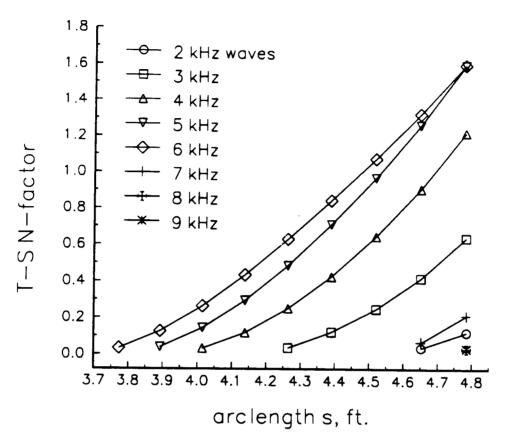

Figure 9: T-S N-Factors in Long Mach 2.4 Square Nozzle

# 3.5 Summary of Square-Nozzle Design Effort

The design, construction, and shakedown of high speed quiet-flow nozzles is a difficult task in which many poorly understood tradeoffs have to be made. All of the difficult high-speed transition phenomena that the nozzles are intended to study must be estimated in order to best design the nozzles. Fabrication costs are difficult to estimate in advance.

The square nozzle concept put forward by Ivan Beckwith of NASA Langley was suggested as a possible method of obtaining the advantages of both axisymmetric and rectangular (2D) nozzles. The walls are flat downstream of the expansion, facilitating the use of windows. The nozzle can be disassembled to facilitate polishing and maintenance of the critical throat region. High Mach number square nozzles can be machined without excessive difficulties with throat tolerances, and contour flaws do not focus to the centerline. All four walls see the same accelerating flow, so it was hoped that crossflow would not be a major problem.

facilitating the use of windows. The nozzle can be disassembled to facilitate polishing and maintenance of the critical throat region. High Mach number square nozzles can be machined without excessive difficulties with throat tolerances, and contour flaws do not focus to the centerline. All four walls see the same accelerating flow, so it was hoped that crossflow would not be a major problem.

The studies carried out to date do not support the high hopes initially conceived. Estimates based on the crossflow Reynolds number (Alcenius) suggested that crossflow would be a major difficulty in these nozzles, even in the throat. These estimates have apparently been confirmed by unpublished e\*\*N estimates carried out by the High Technology Corp. under the SBIR program. It remains possible that the throat-region crossflow-transition problem identified by these computations could be ameliorated by moving the bleed slot downstream. The cost of machining such a nozzle remains a topic of speculation. It may still be that square nozzles will prove to be more cost-effective than axisymmetric or 2D designs. The research to date seems somewhat discouraging but far from conclusive.

# 4 Measurements of Crossflow Instability on the Sidewalls of the LaRC Mach 3.5 Low Disturbance Tunnel

Part of the proposed crossflow investigations involved measurements of the flat side-wall boundary layers in the Mach 3.5 low disturbance tunnel at Langley. These were to be carried out during summer 1994 by Christine Haven, as part of her M.S. thesis at Purdue. One and a half days of tunnel access were provided in the middle of the summer, after about a month of preparation. Although the hot wires, traverse system, and controller software worked acceptably, major difficulties with electronic noise were encountered. Although the cause of these difficulties was later determined, the problem could not be solved in time to allow obtaining low-noise data. The high noise level and the limited amount of data that could be obtained has precluded any attempt to draw definite conclusions from this work. A full report will be provided with the final report on Langley grant NAG-1-1607, which should be forthcoming in a few months.

## 5 Summary

This grant enabled the successful development of a new kind of low cost quiet-flow wind tunnel at Purdue. Since this wind tunnel is the basis for current AFOSR-

supported research, the outcome of the grant has involved successful technology-transfer to AFOSR. The grant also supported the development of relatively efficient and user-friendly software for quiet nozzle design, although the full potential of this software has yet to be put to use. Finally, the grant supported the design and preliminary evaluation of the new square nozzle concept for quiet-flow wind tunnels. Although the preliminary evaluations of this concept are somewhat discouraging, further research might yet show that square nozzles will be an advantageous choice in certain circumstances.

## 6 Acknowledgements

Part of the work described here was carried out by Timothy Alcenius and Christine Haven, whose M.S. thesis research was in part supported under NASA Langley grant NAG-1-1607. The progress described here would not have been possible without the close cooperation and encouragement of Ivan Beckwith, Steve Wilkinson, Dennis Bushnell, Frank Chen, and other Langley personnel. Construction of the Purdue Ludwieg tube was supported in part by a gift in memory of K. H. Hobbie. And, although Langley support for this work is at present terminating, the Purdue work in the area of high-speed transition is able to continue, thanks to support from AFOSR under grants F49620-94-1-0067 and F49620-94-1-0326, monitored by Dr. L. Sakell.

### A Source Code for SIVINPUT

```
PROGRAM SIVINPUT. Fortran-77. For generating input deck to
  Sivells nozzle design code (AEDC-TR-78-63).
   emailed back 'From moen Wed Nov 25 12:00:09 1992' after use by him.
     this program writes an input file in the correct format for
С
      sivells code; sps 6-27-90
С
     modified 9-30-92 for the square nozzle work with streamlines sps
С
С
     modified to produce starting streamlines on nozzle wall.
     mod\ sps\ 11-30-92 to make\ mp=5
     mod 11-30 sps to allow choices of IN, XC, IX
     add header info. 1-16-95, this is the current version used by Alcenius
       for his MS thesis and square nozzle computations (see appendix of
       Alcenius MS thesis).
С
      character*10 title
      character*20 sivfile
     write (*,*) 'enter a rootname to write sivells input file:'

## B Output Subroutine Written for Sivells Code

The following is the subroutine added to the Sivell's code to generate output files for transfer to the boundary-layer code.

```
* subroutine wrtobl.for
* this subroutine modified from perfc by s schneider 6-90 to write sivells
* output to a file to be read directly by a bl program.
* also computes the upstream contour from halls assumptions and rc
* assumes throat is 0,0, and uses formulas from Hall, (3) and
* assumes sf=0.0 at beginning so throat radius is 1 unit
* modified 7-31-91 to give full reference to block CONTR same as elsewhere
* modified 9-29-92 to output multiple calls when writing streamlines,
* also start z write at Mach > 1
* dimension arrays in parameter statement. Note arrays must match with
* other routines. Change small from 0.05 to 0.01
```

```
* modified 9-30-92 to find streamline shapes in transonic region
* mod 11-25-92 to increase array sizes and use parameter statements sps
* mod 6-4-93 to call hophill to do hopkins-hill upstream of throat, sps
* mod 9-1-94 to write out WALTAN and sd with contour for Gortler, sps
      SUBROUTINE wrtobl
                                                                                    1

### C Sivells-to-Harris Interface Code

```
* PROGRAM MAKEBLIN.FOR.

* Steven P. Schneider Purdue University 317-494-3343

* this is a program to read in output from the sivells code,

* add specifics for Re, and write in a form readable

* by the Harris code for bl.

* specific for the nozzle block problem sps 6-90

* add some code for the contraction computation 12-5-90 sps

* add code for output of file for arbitrary shape using modified Newtionian thy

* sps 3-6-91
```

```
* allow for arbitrary power-law distribution of points 3-6-91 sps,
  and for easy change of jsolve
* add code for reading in pressure data from euler code, and shock location
  data, and writing an output file for the harris code 7-13-91 sps
* modified to fix bug with error code on different case 7-28-91 sps
* modify a bit to use with whole nozzle, not just sivells part 2-4-92 sps
* modify to make print stations go to te of nozzle, not just near. 4-8-93 sps
* modify 8-94 to make thermal BC explicit, add bullet solution
* modify 9-8-94 to skip 4 lines in sivells for new sivells radcur format, sps
     parameter(maxpts=1000, jsolve=1)
* jsolve is the number of solution stations per station of input data
   can increase to make finer resolution solution possible
     character*80 text
     character*20 root, infile, outfile, parmfl, tawfile
* most of these are the number of stations along the moc soln
  ss is the number of stations in bl soln to get
     dimension x(maxpts),y(maxpts),pepo(maxpts),s(maxpts),theta(maxpts)
     dimension proval(maxpts),prntval(maxpts),ss(jsolve*maxpts)
     dimension tw(maxpts)

## D Harris to e\*\*MALIK Translation Code

```
* BLTOSTAB.FOR
* this is a program to take vgblp data and put in E**MALIK form
* sps 7-2-90
* revised 7-9-90 to fit with input form provided by Maliks vgblp program,
   different from that implied in preliminary paper
* revised 7-17-90 to fix problem with getting correct matches
    also revised to give correct scaling of profiles for emalik code
* revised 7-18-90 to scale before passing to utder, makes cutoffs clearer
* revised 7-16-91 to write more info to .cur file sps
* revised 7-16 and 7-17-91 to get better derivatives of surface shape sps
   and also to skip past unused iterations printed using variable entropy
   computations
* revised 8-27-91 to use derivative data now output by Harris code
   harris code outputs FZ and TZ, which is actually the derivs wrt the
   wall-normal coordinate eta at the next streamwise solution station.
   However, we do not normally output every single solution station, so
   cannot just use this at the next solution station output. So accept
   the error involved in using the derivs at next solution station in
   place of derivs at current, for now.
* mod. 5-27-94 to read and compute derivs in double, needed for t profiles
* mod. 9-2-94 sps to read derivs of nozzle contour from .bl sivells file
* (couldnt get good derivatives of nozzle contour from printed data)
* mod 9-9-94 to interpolate sivells data, stations don't match, sps
```

```
* mod. 10-14-94 to read curvature data from file when not using sivells, sps
* mod 10-24-94 to use Frank Chen's method of getting curvature from nozzle
     contour data, using old NOS routine, sps.
