Report No. 316/25
Watertown Arsenal

June 7, 1935

Low Chromium 46 Steels

Object

To study the properties of semi-corrosion resisting steels containing 4 to 6% chromium.

Conclusions

Low chromium 46 steels of correct analysis respond satisfactorily to heat treatment. When exposed to the atmosphere or to salt spray, rust appears equally as fast on low chromium 46 steels as on ordinary steels.

The alloy possesses moderate properties and excellent ductility and impact resistance. Its corrosion resistance is not such as to recommend it for ordnance purposes.

Introduction

The oil industry is using considerable quantities of 5% Cr steels because of their resistance to sulphide corrosion and high temperature oxidation.

The value of this material to ordnance was studied and the results are given in this report.

Material

The Allegheny Steel Company, Brackenridge, Pa.,
supplied this Arsenal with steel of the following
analysis:

Analysis of Test Material Supplied by Allegheny Steel
Company, 46 steel, Marked 56A9, Report No. 316/44

<u>Element</u>	<u>%</u>
C	.085
Mn	.46
Si	.330
S	.020
P	.014
Ni	.12
Cr	5.55
Cu	.45
Al	.64

Heat Treatment

The material was heat treated as follows:

Piece A

Heated to 815°C, 2 hrs., furnace cooled
" " 870°C, 2 " oil quenched
" " 700°C, 2 " air cooled.

Piece B

Heated to 815°C, 2 hrs., furnace cooled
" " 870°C, 2 " oil quenched
" " 400°C, 2 " air cooled.

Physical Properties

The properties observed are:

Heat Treatment	870°C O.C. 700°C A.C.		870°C O.C. 400°C A.C.

Machinability

In the softened condition difficulty was encountered in threading. The stock was tough but otherwise was machinable.

Corrosion Resistance

The behavior of this material when exposed to the atmosphere and to salt spray was observed and compared with mild steel. No benefit was detected

by adding 5.55% Cr to steel to retard either the initial period for rusting to be observed or the initial corrosion which occurred.

Discussion

The low chromium 46 steels are commercially available in various grades, viz:

Chromium 4 - 6 %

Carbon .21 to .25%: .16 to .20%: .11 to .15%:
.10% max.

Molybdenum .40 to .60%: .61 to 1.0%: 1.01 to 2.0%

Silicon 1. to 2.%

Titanium .5 to .7%

Tungsten .75 to 1.25%

The other common elements are nominal, for instance; Mn 0.5 max; P 0.04 mx; S 0.04 mx; Si 0.50 mx unless special.

The physical properties of such steels are given on the accompanying tables. A wide range in properties are available. This Arsenal has been supplied with castings of this type analysis for pintle stock.

The addition of more than 2 - 3% Cr reduces the corrosion rate of steel in aerated water, HCl, H₂SO₄, NaCl, NaCl + H₂S, when corroded over long periods of time. The resistance to oxidation is also increased. To enhance the corrosion resistance to acid media, the addition of 0.5 to 1.0% Cu is advocated. To enhance the corrosion resistance to oxidation at high

temperatures, the addition of 0.5 to 1.0% Al is advocated. The addition of 0.5% Mo or of 1.0% V increases the strength at high temperatures and also tends to raise the corrosion resistance. Adding five to eight times as much Titanium as there is carbon causes the steel to lose its air hardening properties so that tensile strength of only 60,000 to 65,000 p.s.i. are obtainable. However, the high temperature strength is not impaired. The tying up of carbon in the form of TiC relieves that much more Cr for enhancing corrosion resistance such as resistance to high temperature oxidation. The alloy finds its usefulness in commerce for its high temperature properties and resistance to oxidation and resistance to crude oils at high temperatures.

For ordnance material the Ordnance Department is interested in ferrous materials which have low initial rates of corrosion rather than low rates of corrosion over long periods of time. The fact that the 5% Cr steels rusted as quickly as plain steels in the atmosphere or salt spray would indicate that this material is not of interest from the corrosion point of view.

Respectfully submitted,

P. R. KOSTING
