Metallurgical Examination of
Two Heavy Cast Armor Plates

Purpose

The purpose of this investigation was to study the metallurgical characteristics of samples cut from the centers of a 3-inch cast plate and a 15 inch grate casting manufactured by the Continental Roll and Steel Foundry Company.

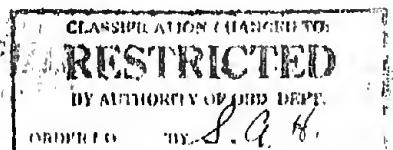

Introduction

It was reported that the 3" plate was generally sound, but that due to a few local casting defects it failed under the impact of a 75 mm. shell. The 15" grate casting also failed under the impact of a 6" shell presumably also because of foundry defects. Two samples from each of the two plates were submitted with a letter dated December 14, 1940 written by Mr. R. O. Henslett, General Metallurgist, Continental Roll and Steel Foundry Company.

Conclusions

The results of this investigation indicate that the failure of the material is due to the following factors:

1. Unsound metal due to casting defects, see Figure #1.
2. Extremely large grain size, see Figure #5.

Results

1. Chemical Analyses

The chemical analyses of the two castings are:

Casting	C	Mn	P	S	Si	Ni	Cr	Mo	V	Cu
3" Plate	.32	.82	.018	.024	.480	1.44	1.13	.51	.16	.056
15" Grating	.40	.83	.022	.032	.505	1.44	1.13	.49	.16	.058

2. Macrostructure

A. Deep Etching

Interior of 3" Cast Armor Plate

Area "A" - The metal shows a quite coarse dendritic structure throughout with prominent interdendritic segregates and occasional small cracks.

Area "B" - The macrostructure and the dendrites in this section are as coarse as those described for Area "A", but the interdendritic segregates are not as extensive.

Interior of 15" Grate Casting

Area "A" - A reasonably fine dendritic structure is seen throughout this section. The segregations noted are similar to sulphide-rich impurities.

Area "B" - This metal shows very heavy segregations in the mid-wall portion, and short quite prominent cracks.

3. Oberhoffer's Etch

Interior of 3" Plate

Area "A" - The metal shows a coarse dendritic structure.

Area "B" - The metal shows a mixture of fine and coarse dendritic structure.

Interior of 15" Grating

Area "A" - A medium coarse dendritic structure is present.

Area "B" - A fairly coarse dendritic structure is evident.

3. Microscopic Examination

Microscopic examination of samples cut from the 3 inch plate and the 15 inch grate casting showed in each case fairly well distributed nonmetallic inclusions. The amount of nonmetallics evident was considerable; and although no information is available to indicate a detrimental effect, it is believed desirable to reduce the amount of nonmetallics as much as possible.

The general structure was sorbitic and the materials possessed a very coarse grain size of Number 1 rated on the A.S.T.M. grain size scale. Only traces of net work grain boundary carbides were evident.

4. Heat Treatment

The heat treatment of the two heavy cast armor plates is as follows:
Heated to 1600°F in 22 hrs., held 12 hrs. - slow cooled with furnace.

"	" 1650°F	" 17 "	"	" "	- normalized.
"	" 1600°F	" 10 "	"	" 20 "	- water quenched.
"	" 1575°F	" 9 "	"	" "	- " "
"	" 1225°F	" 6 "	"	" "	- slow cooled with furnace.
"	" 1250°F	" 10 "	"	" "	- " " "

5. Physical Tests

The results of physical tests made on the 3 inch and 15 inch castings are as follows:

Casting	V.S.P. Lbs./Sq. In.	T.S. Lbs./Sq. In.	Elong. %	Cont. of Area %	Appearance of Fracture
3" Plate Area "A"	79,500	105,000	17.0	27.4	45° break, coarse pitted structure, lustrous cavities.
Area "B"	79,000	101,500	10.0	16.2	45° break, coarse pitted structure, large lustrous cavities, large crack on stem.
15" Grating Area "A"	82,500	110,000	17.5	38.4	Partially cupped coarse pitted structure, check on stem.
Area "B"	84,000	84,000	3.0	12.0	90° break, spongy or dendritic structure.

6. Brinell Hardness

Brinell hardness determinations made on samples taken from both castings are given below:

Casting	Brinell Hardness
3" Plate - Area "A"	217, 217
" " Area "B"	217, 217
15" Grating - Area "A"	228, 228
" " Area "B"	228, 228

Test Procedure and Materials

Two bars about 1"x1"x6" marked 50-P and two bars of the same size marked 50-S were submitted for examination. The 50-P bars which were cut from the center of the 3 inch plate were designated as 3" plate Area "A" and Area "B" respectively. The 50-S bars which were cut from

the 15 inch grate casting were designated as 15 inch grating, Area "A" and Area "B".

Metalurgical examination of these samples included chemical analysis, macroscopic examination, microscopic examination, physical tests and hardness surveys.

Discussion

A survey of the chemical analysis indicates that the carbon in the two castings, especially that of the 15 inch grate casting is relatively high. It is believed that a carbon range of .25/.30 would be more desirable for this type of material.

Generally speaking the 3 inchcast plate had quite a coarse dendritic structure with prominent interdendritic segregates and occasional cracks. In the case of the 15 inch grate casting rather heavy segregations associated with quite prominent cracks were present in the mid-wall portion, see Figure #1. The size and distribution of the dendritic segregation in both plates is shown in Figure #2.

Figures #3 to #7 illustrate the microstructure of the 3" plate and the 15" grate casting. Both castings had an A.S.T.M. grain size No. 1. Recent investigations made at Rock Island Arsenal and this Arsenal indicate that a very large grain size such as reported in this material is correlated with poor ballistic properties. It has been determined to date that good quality cast armor should possess a grain size not larger than No. 6 A.S.T.M. grain size. The variation in the ductility values of the two castings, especially that of the 15 inch grate casting

indicated the presence of heterogeneity in the material.

Respectfully submitted,

S. I. Reed,
Research Metallurgist

APPROVED:

S. B. Ritchie,
