20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

A comprehensive test program was conducted on an F-111E aircraft for the purpose of collecting dynamics data, primarily vibration and acoustic data, at selected locations throughout the aircraft under test conditions within the operational envelope of the aircraft. Data were recorded from 133 accelerometers and microphones at 60 test conditions including gunfiring passes. In addition, flight and engine parameter data were also recorded. The test program is documented by presenting the details on the test instrumentation, transducer locations, test procedures and flight conditions. Test results are limited to overall and peak root

mean square (RMS) levels which give a coarse indication of the dynamics environment of the F-111E. Detailed test results will be presented in the parts of this report which will follow.

FOREWORD

This report documents an in-house effort conducted by the Structural Vibration Branch, Structures and Dynamics Division, Flight Dynamics Laboratory, Air Force Wright Aeronautical Laboratories, Wright-Patterson Air Force Base, Ohio.

This investigation was conducted under Flight Dynamics Laboratory Project 2401, Vibration Prediction and Control, Measurement and Analysis, Work Unit 24010401, Dynamics Environment on Current and Future Air Force Flight Vehicles.

The test aircraft was provided by 3246th Test Wing, Eglin Air Force Base, Florida, Mr. R. White (3246th TW/TETT) was the focal point for the test program conducted at Eglin Air Force Base during the July 1978 - September 1980 time period. The test support was provided by the 3246th TW under Test Number 1472TA02, Support of AFFDL F-111 Vibration/Acoustic Testing. AFWAL/FIBG personnel who had primary responsibility for the test program were Messrs D. E. Seely and E. R. Hotz. Other personnel who made major contributions to the success of this effort were Messrs R. D. Talmadge, C. N. Willhite, J. E. Huffman and L. P. Vaughn. Special acknowledgment is due Mrs. Diana Howdyshell for typing the manuscript.

This report is Part I of a planned number of parts concerned with the F-111E flight test program. Part I presents the details of the test program with test results presented only to give an indication of data trends and data quality. The parts to follow will deal primarily with the spectral and statistical analysis of the recorded data.

This report was released for publication by the authors in August 1981.

SECTION I

INTRODUCTION

One of the most severe problems in airborne equipment design, application, testing, and use is the lack of sufficient data to define the actual dynamic environment under which equipment in the vehicle must operate. In most cases, this lack of data has resulted in: (1) overdesigning the equipment which results in excessive cost, size and weight or (2) underdesigning the equipment with a resulting lack of reliability and limited service life. This problem is even more acute in designing both equipment and structures used in high speed aircraft which must operate in a severe dynamics environment.

To alleviate this deficiency, the Structural Vibration Branch, Structures and Dynamics Division, Flight Dynamics Laboratory, has implemented a comprehensive data acquisition program aimed at obtaining vibration and acoustic data on all available aircraft.

This report describes the flight test program conducted on an F-111E aircraft. The purpose of this program was to collect dynamics data, primarily vibration and acoustics data, at selected locations throughout the aircraft under test conditions within the operational envelope of the aircraft. Additional data including temperature, pressure, air flow rate, and humidity were also collected. The purpose of this report is to document the test program by presenting the details of the test instrumentation, transducer locations, test procedures, and flight conditions. Test results are limited to overall and peak root mean square (RMS) levels which give a coarse indication of the dynamics environment of the F-111E. It is intended that this report be used primarily for selecting transducers and test conditions requiring more detailed data reduction. Detailed test results will be presented in the parts of this report which will follow.

SECTION II

DESCRIPTION OF TEST VEHICLE

The F-111E aircraft, manufactured by the Fort Worth Division of General Dynamics, is a two-place, all-weather, high or low altitude, supersonic, tactical fighter bomber. The aircraft has dual controls and requires a crew of two, seated side-by-side. The aircraft provides the pilot with the in-flight capability to select any angle of wing sweep between 16 and 72.5 degrees. The aircraft has full-span fowler action, double slotted trailing edge flaps, and is powered by two TF30 fan jet afterburning engines internally mounted in the fuselage. The aircraft has a conventional tricycle gear with the main gear as a single assembly. The aircraft has a large vertical stabilizer and a conventional rudder plus ventral strakes located on the lower portion of the engine access doors approximately 30 degrees from the vertical.

The F-111E aircraft used for the test program was Tail Number 68-058. During the period 5 Oct 79 to 18 Sep 80, there were 37 test flights. On each test flight, the aircraft was configured to collect dynamics data for various combinations of internal and external stores. The internal stores included an M61 20MM cannon which was fired on nine of the flights. The aircraft was also flown with two types of experimental fluctuating pressure suppressors (spoilers) installed forward of the weapons bay and a slanted ramp installed in front of the rear bay wall. These devices were being tested to determine their effectiveness in reducing noise in the weapons bay when the bay doors were open.

SECTION III

TEST INSTRUMENTATION

The airborne data acquisition system is shown in block diagram in Figure 1. The system used 104 accelerometers and 29 microphones to measure the vibration and acoustic environment of the aircraft. The type and characteristics of the transducers used to measure acceleration and sound pressure level are summarized in Table 1. In addition to dynamic transducers (accelerometers and microphones), the system used 15 thermocouples, two airflow sensor systems, a humidity sensor, and a pressure transducer to measure slower varying aircraft characteristics. These transducers are summarized in Table 2. In addition, the total instrumentation system included: (1) an in-house fabricated programmable transfer box; (2) a 12-position Ledex, Inc. switch box; (3) a Master six-channel automatic gain changing (AGC) amplifier box; (4) a Secondary six-channel AGC amplifier box, (5) a pair of frequency multiplexers (Microcom Corp. Micromount Model MM402-10) each consisting of two voltage controlled oscillators (VCO) and one mixer amplifier with respective VCO center frequencies and deviations of 128 KHz $\pm$ 16 KHz ($\pm$2.5V) and 176 KHz $\pm$ 16 KHz (+2.5V); (6) a Mars 2000 Tape Recorder; (7) a Base Ten, Inc. Portable Data Acquisition System (PDAS) Data Collector; (8) a time code generator; and (9) voice from the aircraft intercom system.

A complete listing of all transducer identification numbers, locations, and types is contained in Table A-1. Overall transducer locations are illustrated in Figure 2. Figures A-1 thru A-6 are more detailed drawings showing transducer locations. Figure A-7 cross references the transducer number with the Figure numbers (A-8 - A-81) of the photographs which show the precise transducer locations.

Where possible, accelerometers were mounted by using double sided #10-32

Figure 2. Overall Transducer Locations

insulated mounting studs. One side of the stud attached to the accelerometer and the other side attached to drilled and tapped holes in the structure. A single sided stud was used where holes were not allowed. The flat side of the stud was glued to a clean and sanded surface of the structure using Eastman 910 cement and the #10-32 side was attached to the accelerometer. Most of the microphone brackets were installed using a special glue formulated by Eglin personnel. Some of the microphones were installed by drilling and tapping holes to match the microphone bracket mounting holes. All external microphones were flush mounted where possible. Thermocouples which sensed structural temperatures were attached to the surfaces with epoxy. Thermocouples measuring air temperature were suspended in the air. Specific information concerning transducer mounting can be obtained from the photographs in Figures A-8 - A-81.

Each microphone and accelerometer was calibrated in the Laboratory by AFWAL/FIBG to obtain sensitivity and frequency response characteristics. After installation and prior to the initial test flight, the accelerometers were calibrated end-to-end by inserting a known calibration signal at the transducer end of the system and recording the resultant electrical signal on tape. The microphones were calibrated by applying a precise 124dB SPL to each microphone with a Bruel & Kjaer Instruments, Inc. type 4220 Pistonphone and recording this resultant electrical signal on tape. The system calibration was then determined in the Laboratory using the calibration tape.

The complete listing of PDAS input signals is given in Table C-1. In addition to the temperature, airflow, humidity, and pressure sensors mentioned earlier, the PDAS accepted aircraft parameters supplied by other aircraft systems and recorded simultaneously with the signals from transducers. The PDAS Data Collector time division multiplexed all the input signals shown in Table C-1. The system digitally encoded each data sample to a 10 bit binary word which was then converted into a serial pulse code modulation output. The

PDAS system output was 80 k bits/second. The gain status codes from each of the 12 AGC amplifiers and switch position code were also multiplexed by the PDAS.

The signal leads from the 133 accelerometers and microphones were assigned to the 144 inputs of the switch box by the Programmable Transfer Box. Six of the signal leads were paralleled to two or more switch box input slots. The Ledex, Inc. Switch Box had 12 switch positions with 12 signals output for each position of the switch. This permitted switching through 144 input signals 12 at a time. For example, switch position 1 switched in input slots 1-12, switch position 2 switched in input slots 13-24, and so forth. The AGC amplifiers would automatically change gain to provide an optimum input signal level for the recorder and multiplexers. In addition, each amplifier had a gain status output which was a DC level that identified the gain level. These 12 gain status signals were input to the PDAS system. Eight amplifier signals and two frequency multiplexed outputs were then input to the tape recorder as shown in the block diagram (Figure 1). Thus, 4 of the 12 amplifier outputs were frequency multiplexed into 2 tape tracks as shown in the block diagram (Figure 1). Frequency modulation (FM) recording with a center frequency of 54 KHz (Wide Band I) was used for the amplifier outputs, and amplitude modulation (AM) recording was used for the frequency multiplexer and PDAS outputs. Table A-2 shows the transducer ID, tape track (channel), and switch position assignments.

The accuracy limitations of the flight measurement system were due to error contributions from the transducers, signal conditioning equipment, and tape recorder. The maximum error of any one of these elements is unlikely to exceed $\pm$ 5% of full-scale output. A reasonable estimate of maximum likely overall error is the root-mean-square of the errors from the three contributors or 8.7% of full-scale output.

SECTION IV

TEST PROCEDURE

Dynamics data were recorded for test conditions which included ground runup, takeoff, climb, level acceleration and deceleration runs, sideslips, turns, stabilized flight, gunfiring passes, landing, and standard maneuvers. A complete listing of these test conditions including Mach numbers and altitudes is given in Tables 3 and 4. The test conditions listed in Table 4 are more of a transient nature, while those listed in Table 3 are for stabilized flight.

The test coordinator was initially provided a list of the desired flight test conditions. From this list, the test pilot selected the specific test conditions to be flown on each flight or mission. The initial missions concentrated on acquiring data samples throughout the aircraft flight envelope and identifying maneuvers that resulted in higher vibration/acoustic environments.

During a stabilized flight condition, data were recorded simultaneously for 12 transducers that were grouped together on one switch position. The switch was then advanced to the next position and data were recorded for the second set of 12 transducers while the pilot maintained the same stabilized flight condition. This procedure continued until the switch had been sequenced through all 12 positions and data had been recorded for all 133 accelerometers and microphones. Several of the accelerometers and microphones were paralleled onto two or more switch positions in anticipation of a need for time correlation with transducers on these other switch positions. Typical data samples were 20 seconds.

For the flight test conditions which were of a transient nature, (e.g., takeoff, acceleration and deceleration runs, and maneuvers), it was necessary to repeat each test condition for each of the switch positions. In these cases, the tape recorder was turned on just prior to performing the test condition and shut off at completion of the test condition. This resulted in test records in some cases of 3 to 5 minutes in duration. It should be noted that all of the data input to the PDAS

79	1.1	12	Weapon release

(e.g., thermocouple, flight parameters and amplifier gains) were recorded anytime the tape recorder was switched on.

The slow (3-5 minute) aircraft acceleration runs from minimum to maximum Mach numbers at several altitudes were made to allow structural resonances which might be present to build to a peak. These resonances could well occur at Mach numbers for which no stabilized data were to be recorded. When a possible resonance was indicated in playback of the data, the Mach number and altitude for this resonance were determined and a request made to fly this condition in a stabilized test condition.

An operational restriction on the aircraft prohibited acceleration runs with the weapons bay doors open. Therefore, deceleration runs from maximum to minimum Mach number at different altitudes were made with the weapons bay doors open. The following bay configurations were tested:

(1) Empty

(2) With M61 20MM cannon installed

(3) With M61 and BDU-8 installed

(4) With two BDU-8s installed

(5) With and without modifications (spoilers in front of bay and slanted ramp at rear of bay)

A total of 37 records of data were recorded during gunfire passes where 14,000 rounds of ammunition were fired by a M61 20MM cannon mounted in the right weapons bay. Each gunfiring pass consisted of 3-4 seconds of continuous firing at a rate of 100 rounds/second. A 2.5 minute waiting period was required between firings for gun cooling time.

On nine of the test flights, the aircraft was carrying either two or four external stores on the wing pivot pylons. The stores included the GBU 10C/B, MK84 and the CTU-2. External stores were released on some of the flights.

Table A-3 relates weapons bay configuration, external store configuration, and M61 gunfiring records with particular flight mission numbers.

SECTION V

DATA REDUCTION AND PRESENTATION

Data tapes recorded on each test flight were copied and sent to AFWAL/FIBG for data reduction. Figure 3 shows a block diagram of the system used to accomplish the playback and processing of the FM, AM, pulse code modulation (PCM), and frequency multiplexed data contained on each test tape. The primary purpose of this initial data reduction was to quickly assess the quality of the recorded data in order to identify any flight instrumentation problems which required correction prior to continuing with the flight test program. This approach for identifying and correcting instrumentation problems aided in improving overall data quality. Approximately 86% of the data are considered usable.

Each data tape was played back and reduced on the system shown in Figure 3. Six channels of data were reduced at a time; this required two passes through the tape to process all twelve channels of dynamics data. During each pass through the tape, six channels of data were stripped out on an oscillograph recorder at a paper speed of 0.1 inches per second with time code printed on the edge of the paper. These stripouts were used in correlating test conditions from the flight test card or log with the data actually recorded on tape. The oscillograph stripouts were also useful in determining the quality of the recorded data. Simultaneously while stripping out the data on the oscillograph each of the six analog data channels was also input to RMS detectors. The RMS detectors had a time constant of 230 milliseconds with a very flat frequency response as shown in Figure 4. The DC output of each RMS detector was input to an analog to digital conversion system simultaneously with the gain status of each AGC amplifier and the instantaneous time read from the time code tape track. These data were sampled at the lowest available digitizing rate of seven samples per second for each input channel. This rate provided more than adequate resolution and could have been lowered to 1 or 2 samples per input channel. This part of the data

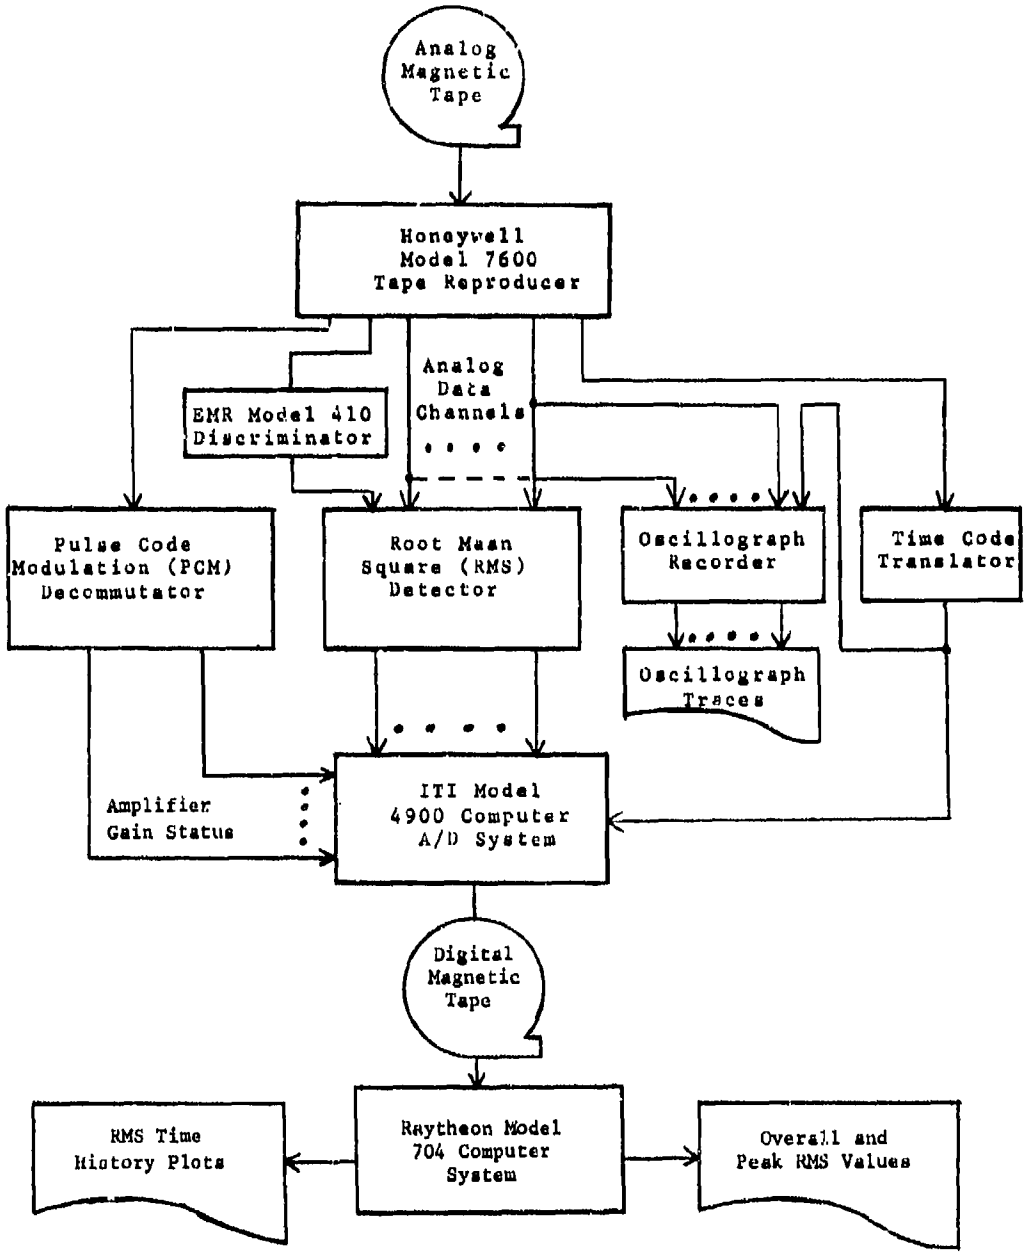

Figure 3. Data Playback and Reduction System

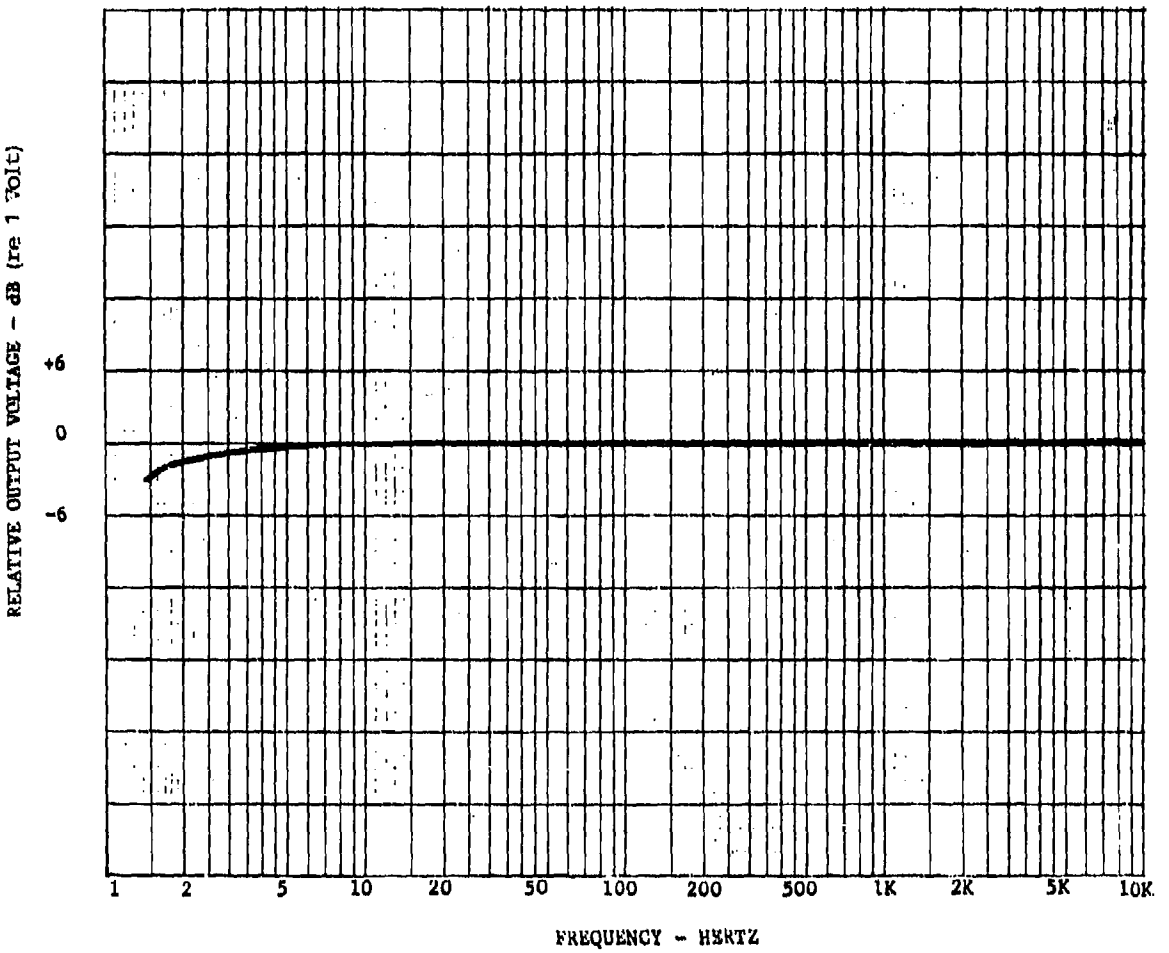

Figure 4. RMS Detector Frequency Response

reduction process was automated; therefore, once the system was set up, the flight tape could be played back in its entirety with no operator assistance required other than rewinding the tape and starting it for the second pass.

The digital tape produced by the analog to digital system was then input to a Raytheon Model 704 computer system along with transducer sensitivities and pickup identification (PUID) codes. Computer software then applied the proper amplifier gain factor and the matching transducer sensitivity to each data sample to produce RMS time history data in engineering units of G-PMS for accelerometer data and dB-sound pressure level for microphone data. Individual RMS time history plots were then made for each transducer for all test records. The initial time history plots revealed a need for additional smoothing to reduce the effects of transients in the data which were directly related to the data acquisition or reduction instrumentation. Examples of these are: a momentary loss of PCM decommutator synchronization signal, change of amplifier gain, and change of switch position. To overcome this problem, a "running average" technique was employed. This averaging technique simply replaced each data point with the average of its amplitude and the amplitude of some specified number of successive data points. It was determined that an eight-point running average produced the desired smoothing. Three typical time history plots are shown in Figure 5. A symbol plotted on the time history curve indicates that during the recording of the data, the signal level exceeded the set upper or lower level limits of the auto-gain ranging amplifier causing the amplifier to step up or down in gain to bring the data signal back into the optimum range of the tape recorder. Printed in the upper right corner of each plot is the initial amplifier gain level in dB (e.g., 40dB = X100 gain) and the actual start time of the record. Any gain change is printed below the starting gain along with the time of occurrence. This information is very useful in performing further data reduction. In addition, the overall RMS level which is computed over the entire test record is printed along

Mission No. 1016, 19 May 80

Test Condition - 9: Left Turn, Max g, Mach 0.85 @ 3K feet

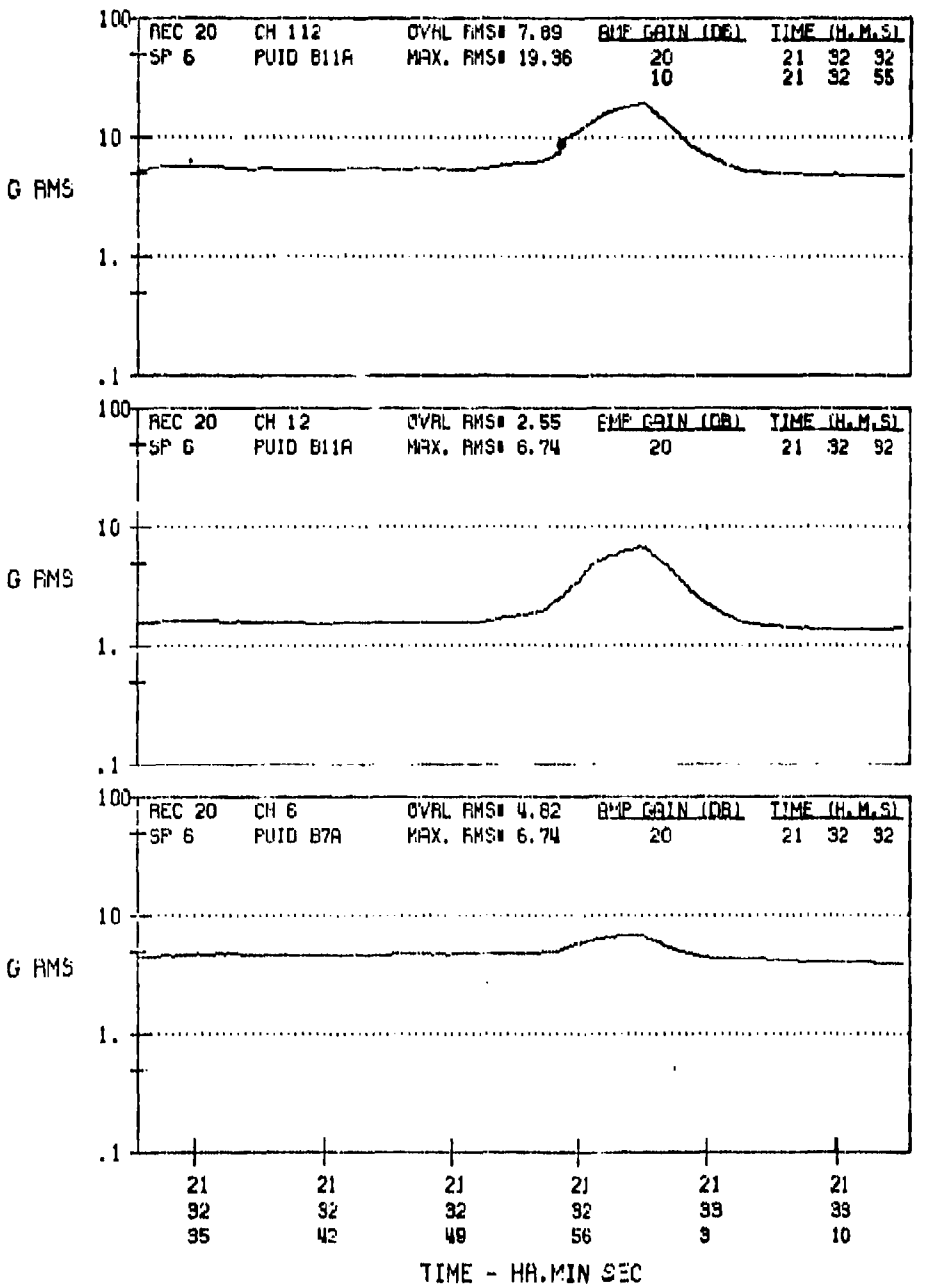

Figure 5 Typical RMS Time Histories

with the maximum RMS level attained during the test record.

Approximately 7200 individual time history plots were produced. Since it is not feasible to include that many plots in this report, it was decided to present this data in condensed but still usable form. About one-half of the time history plots exhibit a relative flat or constant amplitude. Figure 6 shows three typical examples of this type of time history. Data which exhibits this flat amplitude response with time can be represented by its overall RMS level. A list of flight conditions which produced relatively flat amplitude time history responses was given in Table 3. The overall RMS levels for transducer data recorded for these test conditions are given in Appendix B, Table B-1. This table contains the RMS data for each set of 12 transducers for each indicated switch position. In many cases, the same test condition was flown more than once. This is indicated in the tables by consecutive entries of the same test condition code. Time history plots which do not exhibit a flat amplitude level are produced by flight conditions of a transient nature. A list of these flight conditions was given in Table 4. Figure 7 shows three typical examples of time history plots with varying amplitude levels. For this type of data, the maximum amplitude which occurs within a given test record is of more value than the overall RMS. Appendix B, Table B-2 presents maximum RMS levels as read from the time history plots for each transducer.

Data which has been identified as unusable due to instrumentation problems is indicated in Tables B-1 and B-2 by an RMS amplitude of .00. These instrumentation problems were identified during the data editing phase of producing the RMS values. It is suspected that a limited amount of questionable data still remains to be identified. This questionable data probably represents less than 1-2% of the presented RMS data and will be identified during the future spectral analysis phase of data reduction. The spectral analyses will identify the frequency and amplitude of the complex responses which were summed

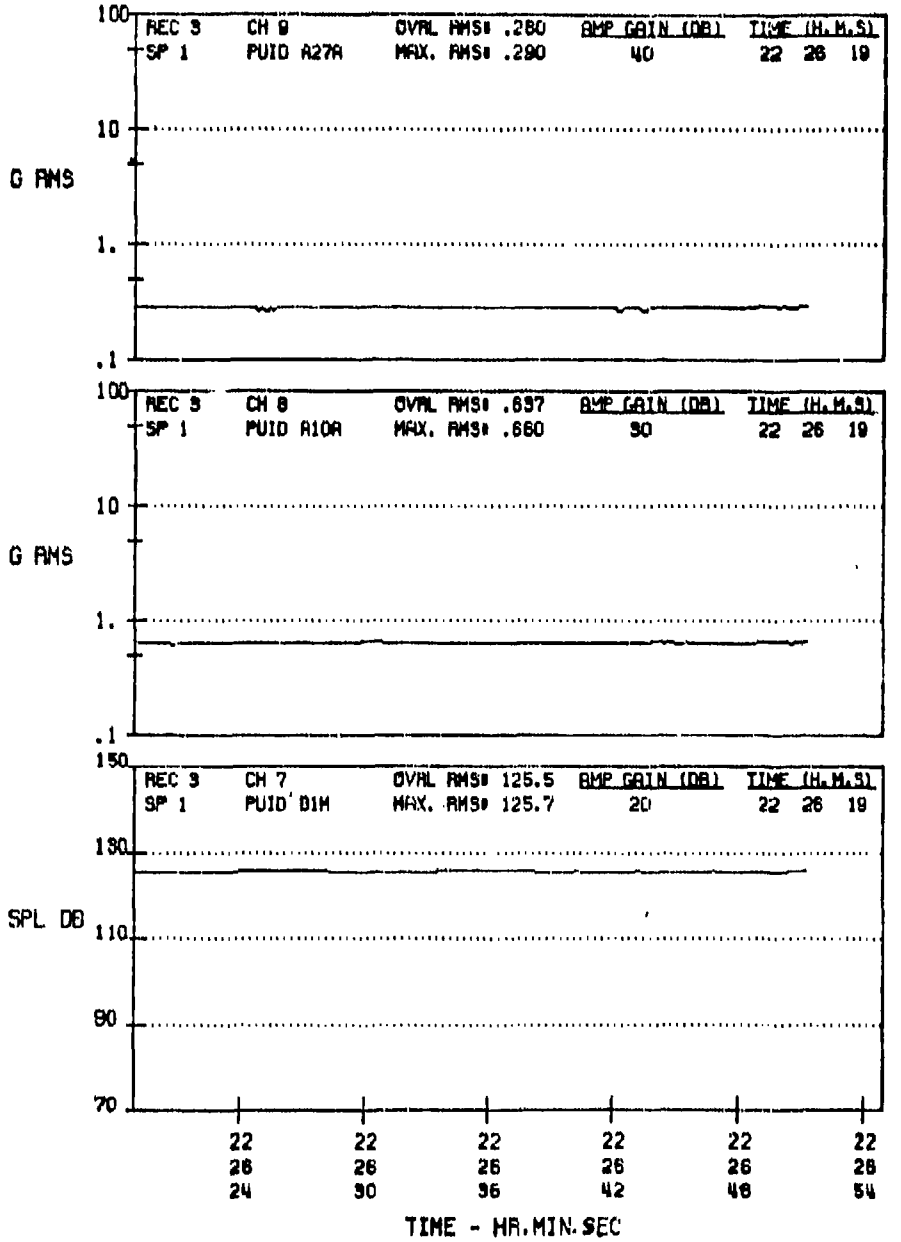

Figure 6 Typical Flat Amplitude RMS Time Histories

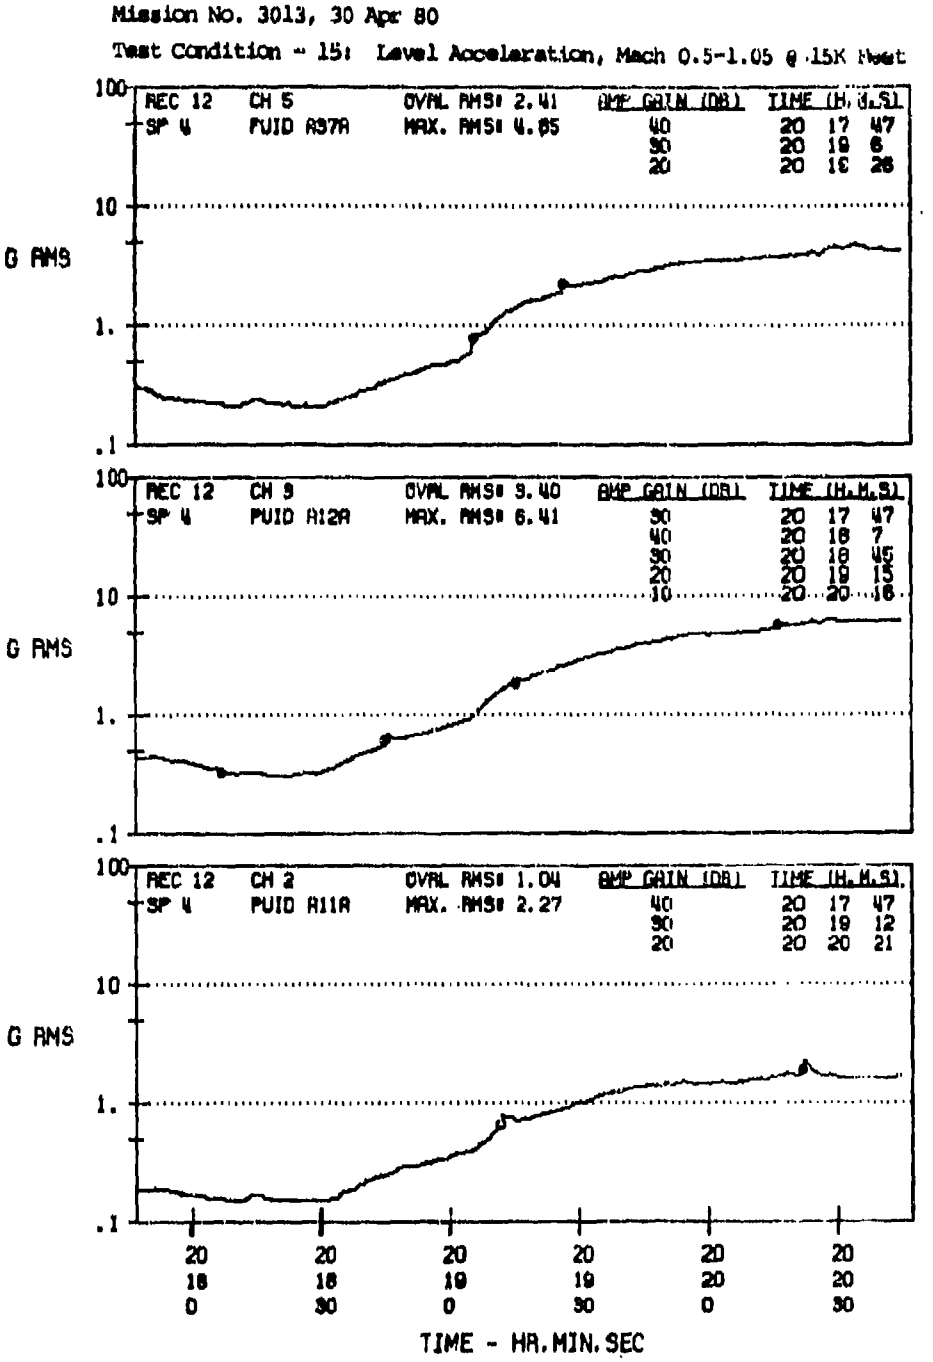

Figure 7 Typical Varying Amplitude RMS Time Histories

in the RMS process to produce each overall RMS amplitude level. This information will be presented in succeeding parts of this report.

Reduction of the large amount of data collected on the PCM channel has been limited to making computer listings of this data at one-second time intervals. These listings were provided by the Math Lab at Eglin AFB FL. Appendix C, Tables C-1 thru C-4 are reproductions of typical listings for each type of printout. These listings are available for later use in correlating aircraft measured dynamic response with flight parameters, temperatures, flow rates, etc.

SECTION VI

PLANNED DATA ANALYSIS

The dynamics data measured on the F-111E will be used in several specific efforts now being conducted within the Air Force. These efforts are briefly described in the following paragraphs.

1. AFWAL/FIBG Work Unit 24010414. The title of this work unit is "Vibration Analysis and Testing Technology". A major part of this work unit is devoted to the development and verification of empirical methods for the prediction of both linear and angular vibration of aircraft structures. Much of the data measured on the F-111E will be used to improve and expand these existing prediction methods. The data will also be used to study a new prediction technique for vibration transmitted from external skin structure to internal compartment sub-structure and equipment. This will involve using measurements from pairs of accelerometers and microphones which were installed at specified locations throughout the F-111E aircraft.

2. AFWAL/FIBE Work Unit 24010146. The title of this work unit is "Acoustics Research". One area being studied under this work unit is internal weapons bay aero-acoustic environments. The internal weapons bay environment immediately before and during weapons release continues to present severe aircraft, weapons design, structural, and operational problems. A substantial part of the F-111E vibration and acoustics test program was conducted to measure the weapons bay aeroacoustic environment with the bay doors open with and without fluctuating pressure suppression devices installed. This measured data will be evaluated to determine effectiveness of the suppression devices in reducing the weapons bay aeroacoustic environment. Initial results of this effort were reported in Reference 2.

3. AFWAL/FIBG Work Unit 24010401. The title of this work unit is "Dynamics Environment on Current and Future Air Force Flight Vehicles". Overall

RMS vibration measurements will be modeled as the sum of a general mean plus a location effect plus a test condition effect plus an interaction constant times the product of these two effects. From these results, locations and test conditions for broad band spectral analyses will be selected. Then spectral magnitudes at each frequency will be modeled in the same way and the results plotted to show on the same graph, the same frequency spectrum of the general mean, the location effect, the test condition effect, and the interaction constant. These results can then, in turn, be used to determine the need for further narrow band analyses. Regression analyses will be employed to model the test condition effects as functions of airspeed, altitude, engine power, etc. Analyses of variance will be used to model location effects in terms of structural characteristics and direction. Factor analyses will also be used to determine the extent to which all spectral plots obtained can be modeled as linear combinations of a few more fundamental plots. This work will be reported in subsequent parts of this report.

4. TN-ASD-AFWAL-2011-75-17(01). The title of this technology need (TN) is "Updated Dynamics Qualification Test Criteria and Techniques" dated 17 Oct 80. The objective of this TN is to refine and augment the dynamic test methods of MIL-STD-810. One particular area to be updated is that which covers gunfire criteria. The gunfire vibration prediction method contained in the present version of MIL-STD-810 was developed prior to 1975. Gunfire data from the F-111E test program and from other recent test programs will be used to evaluate a recently developed simplified gunfire vibration prediction method. Vibration and acoustic data will also be made available for updating other sections of MIL-STD-810 as well.

SECTION VII

CONCLUSIONS

1. A large quantity of vibration and acoustic test data recorded throughout the operational flight envelope of the F-111E is now available for use in dynamics research and development efforts, designing electronic and electro-optical systems, updating dynamics qualification test criteria, and solving present and future operational dynamics problems on the F-111E.

2. To improve the overall quality of dynamics test data on large flight test programs, it is essential that test tapes be played back and reviewed for quality following each test flight with adequate time provided to correct major instrumentation problems prior to continuing the flight test program. The use of an RMS Detector System and time history computer software provides an effective "quick look" method for determining the quality of flight test data.

3. The flight parameter data which was sampled and recorded along with the dynamics data was very useful in correlating aircraft performance with dynamics response. Much of the scatter in the dynamics data can be attributed to the difficulty in maintaining stable flight conditions over the length of test records and the necessity of setting up and repeating flight conditions for each set of 12 transducers.

APPENDIX C

SAMPLE LISTINGS OF TEMPERATURES, FLIGHT PARAMETERS AND OTHER PDAS DATA

TABLE C-1

LIST OF SIGNAL INPUTS TO PDAS

Abbreviation	Signal Description
STABL	Horizontal Stabilator Left
STABR	Horizontal Stabilator Right
PITCH	Pitch
RUD POS	Rudder Position
ROLL	Roll
PITCH R	Pitch Rate
MACH	Mach Number
EPR L	Engine Pressure Ratio, Left
FUEL	Total Fuel
ALT	Altitude
ASP	Airspeed
EPR R	Engine Pressure Ratio, Right
HDG	Heading
SS ANG	Sideslip Angle
A/ATT	Angle of Attack
N2R	N2 Right-Engine Spool Speed
N2L	N2 Left-Engine Spool Speed
YAW R	Yaw Rate
AY	Lateral Acceleration - Ay
RAM T	Ram Air Temperature
RAT	Ram Air Turbine Excitation
ROLL R	Roll Rate
AZ	Vertical Acceleration c.g. - Az
SENSE 8B	Air Flow Sensor Temperature 2B
FLOW 8B	Air Flow Rate 10/20
DIF PR	Differential Pressure - Never Used
GAIN 1 thru GAIN 12	Gain of AGC Amplifiers 1 thru 12
HUM	Relative Humidity
SENSE HUM	Relative Humidity Temperature
ABS PR	Absolute Pressure in Equipment Bay
SENS F 18	Air Flow Sensor Temperature 1B
TC1 thru TC15	Thermocouples Numbers 1 thru 15
FLOW F18	Air Flow Rate 9/14
EVENT	Weapons Switch Off and Weapons Release
F FLOW R	Fuel Flow, Right
F FLOW L	Fuel Flow, Left
STEP	Switch Position
ACCEL 1 thru 15	Flutter Accelerometers 1 thru 15
R ST	Roll, Stick Position
P ST	Pitch, Stick Position
IN DAMP	Inboard Damper - Not Used
C DAMP	Center Damper - Not Used
IN SPOIL	Inboard Spoiler
OUT SPOIL	Outboard Spoiler
PED POS	Rudder Pedal Position
WNG SWP DEG	Wing Sweep Degrees
