13. ABSTRACT (Maximum 200) The objectives are a.) to evaluate the incidence of post-traumatic stress disorder (PTSD) in breast cancer patients and "witnesses" (i.e., significant others), and b.) to validate interview-based diagnoses by measuring physiologic responses during script-driven imagery of patients' and witnesses' personal experiences with breast cancer. To date, of 58 breast cancer patients studied, 4 (7%) met DSM-IV criteria for current PTSD; 11 (19%) for past PTSD; and 43 (74%) patients for neither. In the laboratory, 1 (33%) of 3 current PTSD patients, 1 (10%) of 10 past PTSD patients, and 5 (19%) of 27 never PTSD patients were physiologic responders. Similarly low rates of the PTSD diagnosis and of physiologic responding have been found in 41 witnesses studied. These data call into question "being diagnosed with a life-threatening illness" (DSM-IV, p. 424) as a source of physiologically valid PTSD.

5. INTRODUCTION. While it is clear from research during the past two decades that extreme, acute stressful events such as military combat or violent rape can and do produce post-traumatic stress disorder (PTSD), the ability of less acute stressors to produce this disorder remains unclear. The stressful experiences of having breast cancer diagnosed and treated in oneself or one's loved one are cases in point. Such experiences are often accompanied by subjective reactions of fear, helplessness, and horror, which are elements in diagnostic criteria for PTSD set forth in the *Diagnostic and Statistical Manual of Mental Disorder*, fourth edition (DSM-IV; American Psychiatric Association, 1994). However, although a lesion on a mammogram may represent as much of a threat to a woman's survival as a rapist's knife at her throat, the threat posed by the lesion is less immediate and less palpable.

The objectives of this project are a.) to evaluate the incidence of PTSD in breast cancer patients and their "witnesses" (i.e., significant others), and b.) to attempt to validate interview-based diagnoses of PTSD by using a psychophysiologic technique previously shown by the PI and colleagues (Orr & Pitman, 1993; Orr et al, 1993; Pitman et al, 1987, 1990; Shalev et al, 1993) to significantly discriminate research subjects with PTSD and without PTSD. In the present project, this is being done by measuring psychophysiologic responses during script-driven imagery of the most stressful aspects of patients' and witnesses' personal experiences with breast cancer in themselves or their loved ones.

The project's hypotheses are: A.1.) the incidence of diagnosed PTSD in breast cancer patients is comparable to the incidence of PTSD resulting from other, previously studied, traumatic events; A.2.) the incidence of diagnosed PTSD in breast cancer witnesses is comparable to the incidence of PTSD resulting from other, previously studied, traumatic events; B.1.) physiologic responses during personal imagery of breast-cancer-related experiences are greater in breast cancer patients with PTSD than in breast cancer patients without PTSD; B.2.) physiologic responses during personal imagery of breast-cancer-related experiences are greater in breast cancer witnesses with PTSD than in breast cancer witnesses without PTSD; C.1.) PTSD breast cancer patients' physiologic responses during personal imagery of their breast-cancer-related experiences are comparable to other, previously studied, PTSD subjects' physiologic responses during personal imagery of their traumatic experiences; and C.2). PTSD breast cancer witnesses' physiologic responses during personal imagery of their breast-cancer-related experiences are comparable to other, previously studied, PTSD subjects' physiologic responses during personal imagery of their traumatic experiences.

6. BODY OF REPORT. The project is proceeding as proposed, although recruitment has not fulfilled projections. Despite our strenuous efforts, we have not received the cooperation we had hoped from local physicians in referring suitable subject candidates to us from their busy office practices.

As of the end of the project's 03 year, we had conducted personal interviews on 58 breast cancer patients. From the psychodiagnostic standpoint, using the Clinician-Administered PTSD Scale (CAPS; Blake et al, 1995), 4 (7%) met DSM-IV criteria for current PTSD related to their breast cancer experiences; 11 (19%) patients met DSM-IV criteria for past but not current (i.e., lifetime) PTSD; 43 (74%) patients met DSM-IV criteria for neither current nor past (i.e., never) PTSD. As of the end of the project's 03 year, we had conducted personal interviews on 41 witnesses. Of the 41 witnesses, 1 (2%) met DSM-IV criteria for current PTSD related to their experiences of their significant others' breast cancer: 5 (12%) met DSM-IV criteria for past PTSD; 35 (85%) met criteria for neither current nor past PTSD.

As of the end of the project's 03 year, we had studied 40 breast cancer patients and 28 witnesses in the psychophysiology laboratory. We applied to these subjects' responses an a priori discriminant function derived from the physiologic responses of 46 PTSD subjects and 48 non-PTSD subjects who had experienced other traumatic events and previously been studied in the same procedure. Of the 3 patients diagnosed current PTSD, 1 (33%) was a physiologic responder. Of the 10 patients diagnosed past PTSD, 1 (10%) was a physiologic responder. Of the 27 patients diagnosed never PTSD, 5 (19%) were physiologic responders. Of the 1 witness diagnosed current PTSD, 0 (0%) was a physiologic responder. Of the 6 witnesses diagnosed past PTSD, 2 (33%) were physiologic responders. Of the 21 witnesses diagnosed never PTSD, 3 (14%) were physiologic responders. The rate of physiologic responders among previously studied trauma-exposed subjects are: current PTSD 56%, past PTSD 47%, never PTSD 13%.

We have also completed telephone interviews using a modified version of the PTSD Check List (PCL) on 22 additional subjects (16 patients, 5 witnesses), 9 of whom are scheduled to come in for interview and psychophysiology testing. Of these 16 patients, 1 had presumptive current PTSD. Of these 6 witnesses, 1 had presumptive past PTSD.

7. CONCLUSIONS. If the present trends continue, it is unlikely that any of the project's hypotheses will be confirmed. As indicated in the Introduction, this would not be entirely

Principal Investigator: Roger K. Pitman, M.D.

unanticipated. The data obtained to date call into question "being diagnosed with a life-threatening illness" (DSM-IV, p. 424) as a source of physiologically valid PTSD.

MEMORANDUM FOR Administrator, Defense Technical Information
Center (DTIC-OCA), 8725 John J. Kingman Road, Fort Belvoir,
VA 22060-6218

SUBJECT: Request Change in Distribution Statement

1. The U.S. Army Medical Research and Materiel Command has reexamined the need for the limitation assigned to the technical reports listed at enclosure. Request the limited distribution statement for these reports be changed to "Approved for public release; distribution unlimited." These reports should be released to the National Technical Information Service.

2. Point of contact for this request is Ms. Judy Pawlus at DSN 343-7322 or by e-mail at judy.pawlus@det.amedd.army.mil.

FOR THE COMMANDER:

Encl

PHYLLIS M. RINEHART
Deputy Chief of Staff for
Information Management
