PISTON DECELERATION SYSTEM

4

5

STATEMENT OF GOVERNMENT INTEREST

6

The invention described herein may be manufactured and  
7 used by or for the Government of the United States of America  
8 for governmental purposes without the payment of any royalties  
9 thereon or therefor.

10

11

BACKGROUND OF THE INVENTION

12

(1) Field of the Invention

13

This invention generally relates to a device for enabling  
14 a quiet ejection of launched items from a launch tube. More  
15 particularly, the invention relates to piston deceleration  
16 system utilizing an arrangement and shape of bumpers and a  
17 modified piston shaft.

18

19

(2) Description of the Prior Art

20

The current art for submarine launch systems for three  
21 inch devices was developed in the early 1960's. The launch  
22 systems utilize a basic design as shown and described in  
23 connection with FIGS. 1A-1C, hereinbelow. Because these

1 systems create a cavitation or water hammer during launch,  
2 they are incapable of conducting a quiet launch.

3 Thus, a problem exists in the art whereby it is necessary  
4 to remove the cavitation or water hammer effect in order to  
5 produce a quiet launch.

6 The following patents, for example, disclose various  
7 types of piston control, but do not disclose an arrangement  
8 and shape of pistons or shaft as does the present invention  
9 which permits a quiet launch.

10 U.S. Patent No. 4,561,248 to Quin et al.;

11 U.S. Patent No. 4,609,135 to Elliesen;

12 U.S. Patent No. 5,224,413 to Herner; and

13 U.S. Patent No. 5,850,776 to Takeuchi et al.

14 Specifically, Quin et al. disclose a hydraulic shock-  
15 absorbing jack particularly for use underwater which includes  
16 a cylinder in which a piston associated with an actuated rod  
17 is slidable. The piston defines within the cylinder a first  
18 actuating chamber provided with a first inlet for actuating  
19 liquid and connected to an accumulator of elastically variable  
20 volume, and a second actuating chamber provided with a second  
21 inlet for actuating liquid. The rod is mounted to be slidable  
22 relative to the piston such that, in the event of a shock  
23 applied to the rod which would otherwise cause an increase in  
24 the volume of the second chamber, the rod alone moves relative

1 to the piston without affecting the volume of the second  
2 chamber. The rod is provided with an enlarged head located in  
3 the first chamber and preventing its disengagement from the  
4 piston.

5 The patent to Elliesen discloses a sound-dampened driving  
6 apparatus for fasteners wherein a main valve means is arranged  
7 above a working cylinder of the apparatus and movable within a  
8 cylindrical bore. When the main valve means is in its lower  
9 at rest position, the main valve means separates the working  
10 cylinder from a source of compressed air and connects the  
11 cylinder to the atmosphere. When the main valve means is in  
12 its upper actuating position, the working cylinder is  
13 connected to the source of compressed air and the valve means  
14 blocks the cylinder connection to the atmosphere. The space  
15 above the main valve member within the cylindrical bore is  
16 capable of being alternately connected to either the  
17 atmosphere or compressed air, and includes a sound dampening  
18 means arranged in the space above the main valve member.

19 Herner discloses an impact dampening ring having a  
20 primary bumper and a secondary bumper for dampening the  
21 engagement of a piston against and end of a power cylinder.  
22 The primary bumper has a curved or arcuate surface for initial  
23 engagement with the end of the cylinder and the secondary  
24 bumper has a flat surface for secondary engagement with the

1 end of the cylinder. The engagement of the primary and  
2 secondary bumpers dampens the impact and prevents the piston  
3 from directly engaging the end of the power cylinder. A  
4 mounting flange on the impact dampening rings provides a means  
5 for mounting the impact dampening ring onto a mounting surface  
6 of the piston. A seal along the outer perimeter of the impact  
7 dampening ring provides a fluid tight seal for the piston  
8 inside of the power cylinder.

9       Takeuchi et al. disclose a fluid pressure cylinder  
10 including a cylinder body, a piston accommodated in the  
11 cylinder body to define first and second pressure chambers  
12 therein, means for supplying fluid to each chamber to  
13 reciprocate the piston between a first stroke end and a second  
14 stroke end, first and second bumper surfaces, an annular  
15 cushion retainer connected to the first bumper surface, and an  
16 elastomeric cushion for deforming and cushioning an impact  
17 produced when the piston reaches the first stroke end. The  
18 bumper surfaces approach each other when the piston reaches  
19 the first stroke end and separate from one another when the  
20 piston moves toward the second stroke end. The cushion has a  
21 shape corresponding generally to a hollow conical section.  
22 The cushion includes a base section retained by the cushion  
23 retainer and a buffer section joined to the base section. The  
24 buffer section has an outer surface for contacting the second

1 bumper surface and an inner surface that faces the first  
2 bumper surface. The outer surface forms a circular seal with  
3 the second bumper surface when the piston approaches the first  
4 stroke end. The cushion is flexed such that the buffer section  
5 moves toward the first bumper surfaces. The buffer section  
6 moves away from the first bumper surface when the piston moves  
7 towards the second stroke end.

8 It should be understood that the present invention would  
9 in fact enhance the functionality of the above patents by  
10 providing both a unique arrangement and shape of shock  
11 absorbing members within a launcher impulse tank assembly and  
12 structuring the piston assembly itself to aid in the shock  
13 absorption of the piston stroke.

14

15

#### SUMMARY OF THE INVENTION

16 Therefore it is an object of this invention to provide a  
17 piston deceleration system for absorbing a piston shock at one  
18 end of the stroke.

19 Another object of this invention is to provide a piston  
20 deceleration system utilizing a unique arrangement of  
21 deflection bumpers for reducing shock within an impulse tank  
22 assembly.

23 Still another object of this invention is to provide a  
24 piston deceleration system utilizing a unique shape of

1 deflection bumpers that prevents cavitation within an impulse  
2 tank assembly.

3 A still further object of the invention is to provide a  
4 piston deceleration system which is integrated into existing  
5 piston systems without substantial modification.

6 Yet another object of this invention is to provide a  
7 piston deceleration system which is simple to manufacture and  
8 easy to use.

9 In accordance with one aspect of this invention, there is  
10 provided a piston deceleration system including an elongated  
11 piston shaft, a piston member slidably seated on the elongated  
12 piston shaft, a tank member having a first opening formed in a  
13 first end surface thereof and a second opening formed in a  
14 second end surface thereof, the elongated piston shaft being  
15 reciprocally inserted into the tank member through the first  
16 end surface. An intermediate stop limit member is formed on  
17 the elongated piston shaft between the piston member and the  
18 first end of the tank member. A shaft shock absorbing member  
19 is positioned between the stop limit member and the piston on  
20 the elongated piston shaft, and a piston shock absorbing  
21 members is positioned between the piston member and the second  
22 end of the tank member on the elongated piston shaft. Each of  
23 the plurality of shock absorbing members absorbing a shock of  
24 the reciprocating piston member.

BRIEF DESCRIPTION OF THE DRAWINGS

The appended claims particularly point out and distinctly claim the subject matter of this invention. The various objects, advantages and novel features of this invention will be more fully apparent from a reading of the following detailed description in conjunction with the accompanying drawings in which like reference numerals refer to like parts, and in which:

FIG. 1A is a side sectional view of a prior art launcher impulse tank assembly;

FIG. 1B is a side sectional view of a prior art bumper for the impulse tank assembly of FIG. 1A;

FIG. 1C is a side sectional view of another prior art bumper for the impulse tank assembly of FIG. 1A;

FIG. 2 is a side sectional view of the launcher impulse tank assembly according to a preferred embodiment of the present invention having deflection bumpers therein;

FIG. 3 is a sectional view of deflection bumpers mounted on a movable shaft/piston assembly according to a preferred embodiment of the present invention;

FIG. 4A is a side sectional view of a deflection bumper according to the present invention;

FIG. 4B is a reverse sectional view of a deflection bumper according to the present invention; and

1           FIG. 5 is a side sectional view of a launcher impulse tank  
2 assembly according to a second preferred embodiment of the  
3 present invention.

4

5                                   DESCRIPTION OF THE PREFERRED EMBODIMENT

6           In general, the present invention is directed to an  
7 apparatus for providing a quiet ejection of devices from a  
8 submarine.

9           In FIG. 1A there is shown a submarine small device launch  
10 systems utilizing a basic design concept which was developed  
11 in the early sixties. In operation, an impulse tank assembly  
12 10 is connected to a high pressure air source 12 on one side,  
13 and to a 3 inch launch tube on the other side. The assembly  
14 10 more specifically includes an impulse tank portion 16  
15 having an air side end cap 18 and a water side end cap 20.  
16 The air side end cap 18 includes an inlet/outlet portion 22  
17 through which a high pressure air source is received and spent  
18 air is exhausted. The water side end cap 20 includes an  
19 outlet 24 through which water is forced to the launch tube 14.  
20 Within the outlet 24 there is formed a known assembly of  
21 deceleration disks 26. A piston shaft 28 is slidably inserted  
22 through a shaft aperture in the air side end cap 18 and  
23 terminates in a conical end portion 30 interior of the  
24 deceleration disks 26. A piston member 32 is mounted on the

1 piston shaft 28 behind the conical end portion 30 of the  
2 shaft. The piston member 32 pushes against the water side end  
3 cap 20.

4 In the conventional impulse tank assembly 10 of FIG. 1A,  
5 there is an arrangement of bumpers 34, 36 for assisting in the  
6 deceleration of fluid through the water side end cap 20 on the  
7 way to the launch tube 14. While the general shape of the  
8 bumpers is rectangular in cross-section, upon closer  
9 inspection of FIG. 1B and 1C, it is shown that some of the  
10 bumpers are a plug shape with an end flange at 34 and some of  
11 the bumpers have a peaked cap shape as in bumpers 36. The  
12 bumpers 34 are mounted on the inner surface of the air side  
13 end cap 18 and the bumpers 36 are mounted on the inner surface  
14 of the water side end cap 20.

15 When it is desired to fire a device from the launch tube  
16 14, high pressure air from source 12 is ported to the tank 16.  
17 This forces the piston 30 within the tank 16 to push water,  
18 which is on the side of the piston adjacent to the launch tube  
19 14, to the breech end of a launch tube 14. As this air  
20 pressure is higher than sea pressure, a pressure imbalance is  
21 created between the muzzle end of the launch tube and breech  
22 end of a device to be launched (not shown) in the launch tube.  
23 This results in the device being ejected from the launch tube.  
24 As a submarine goes deeper under water, the sea pressure on

1 the muzzle of the launcher becomes greater. Therefore, the  
2 high pressure air source must utilize higher and higher  
3 pressure to satisfactorily effect a launch.

4 In operation, as the piston member 32 reaches an end of  
5 its stroke, there would be a metal to metal impact if  
6 provisions were not incorporated into the system design to  
7 prevent such an occurrence. Such contact would not only  
8 result in shock to the system's hardware but also result in a  
9 high level of air-born and water-born noise from the  
10 submarine. In order to reduce the effect of the end of stroke  
11 impact, the rubber bumpers 34, 36 are incorporated into both  
12 end caps 18 and 20 of the impulse tank 16 and the water side  
13 of the impulse tank incorporates the deceleration disks 26  
14 therein. Bumpers 34 and 36 are solid, rubber rings which are  
15 bolted to end caps 18 and 20.

16 Referring now more particularly to FIGS. 1B and 1C, it  
17 can be seen that the known bumpers are represented by pieces  
18 of rubber shown in cross section. When the piston 32 contacts  
19 these bumpers, they prevent metal to metal contact but do very  
20 little to slowly mitigate the energy which is pushing the  
21 piston 32 into the bumper 34, 36. This is because rubber is  
22 non-compressible and their design is such that little  
23 deflection takes place. The deceleration disks 26 work in  
24 conjunction with the conical end 30 of the piston shaft 28 to

1 restrict fluid flow from moving from the water side of the  
2 piston member 32 to the launch tube at the end of its power  
3 stroke.

4 As the shaft/piston assembly 28, 32 move toward end of  
5 their stroke, more and more deceleration disks 26 are  
6 effectively sealed against fluid flow by the cylindrical  
7 section of the shaft cone 30. This results in higher and  
8 higher pressure being built up on the water side of the piston  
9 member 32. This pressure counteracts the high air pressure on  
10 the air side of the piston member 32, in an attempt to cushion  
11 the last portion of the piston's travel. However, in spite of  
12 the piston deceleration control effected by the bumpers 34, 36  
13 and the deceleration disk dashpot 26, the column of water in  
14 the pipe leading to the launch tube tends to continue to flow  
15 in the direction of the launch tube. This momentum results in  
16 a low pressure area being created in the area of the launch  
17 pipe, closest to the impulse tank 16. This low pressure  
18 results in a rapid stop of all flow in the pipeline which  
19 creates cavitation or water hammer. The water hammer is  
20 detrimental to the system with respect to its transmitted  
21 shock and vibration loads transmitted to mechanical parts and  
22 detrimental to the ship in that it provides and externally  
23 detectable acoustic event.

1           When the system known in the art (FIGS. 1A, 1B, 1C) was  
2 first developed, this water hammer was inconsequential as the  
3 3 inch launcher was primarily utilized for distress buoys,  
4 marker buoys, broad band jammers and other devices which  
5 themselves revealed ship position. However, the 3 inch  
6 launcher is now used for a myriad of devices which include  
7 bathythermographs, time delay jammers, decoy devices and  
8 other devices where a quiet launch is desirable.

9           Accordingly, the inventors have discovered a modification  
10 to the existing system which is incorporated into the system  
11 with a minimal expenditure of funds and a minimal impact on  
12 existing ship hardware so that ship arrangement problems will  
13 not be introduced.

14           FIG. 2 reflect both improved bumpers and improved  
15 connection between the piston and piston shaft according to a  
16 first preferred embodiment of the present invention.

17           In detail, the device shown in FIG. 2 includes an impulse  
18 tank assembly 40 connected to a controllable high pressure air  
19 source 42 on one side, and to a 3 inch launch tube 44 on the  
20 other side. The launcher assembly 40 more specifically  
21 includes an impulse tank portion 46 having an air side end cap  
22 48 and a water side end cap 50. The air side end cap 48  
23 includes an inlet/outlet portion 52 through which a high  
24 pressure air source is received and spent air is exhausted.

1 The water side end cap 50 includes an outlet 54 through which  
2 water is forced to the launch tube 14. Within the outlet 54  
3 there is formed a known assembly of deceleration disks 56. A  
4 piston shaft 58 is slidably inserted through a shaft aperture  
5 in the air side end cap 48 and terminates in a conical end  
6 portion 60 interior of the deceleration disks 56. A piston  
7 member 62 is slidably mounted on an enlarged portion 66 of the  
8 piston shaft 58 behind the conical end portion 60 of the  
9 shaft. At this point the substance of the present invention  
10 differs from the conventional art described in connection with  
11 FIGS. 1A, 1B, and 1C in the following respects. A water side  
12 deflection bumper 63 is mounted on the inner surface of the  
13 water side end cap 50. An air side deflection bumper 64 is  
14 mounted on the inner surface of the air side end cap 48 and  
15 the inner surface of the water side end cap 50. Deflection  
16 bumpers 63, 64 are ring shaped, rubber bumpers fastened to the  
17 inner surfaces of end caps 48 and 50 by bolts; however,  
18 another mounting method such as an adhesive could be used.  
19 The deflection bumpers 63 and 64 of the present invention  
20 (FIGS. 4A and 4B) are configured such that they need not be  
21 compressed but rather deflect. The amount of desired  
22 deflection can be adjusted and modified to meet the particular  
23 needs of a launch application, however, its configuration is  
24 such that it requires a timed absorption of energy to cause

1 the deflection. As a result of this time factor, the sharp  
2 impact associated with the attempt to compress a non-  
3 compressible material is mitigated.

4 The piston and shaft assembly is likewise different than  
5 that previously known in the art. In particular, the device  
6 of FIG. 1A reflects a piston 32/shaft 28 assembly where there  
7 is no relative motion between these two parts. FIG. 3  
8 reflects the detail of a piston 62/shaft 58 assembly found in  
9 FIG. 2 where the piston 62 can actually slide on a portion of  
10 the shaft 58.

11 The shaft portion 58 includes enlarged portion 66 having a  
12 greater diameter than the diameter of the shaft 58. Portion  
13 66 is joined proximate the conical end portion 60 of the shaft  
14 58. A stop member 68 is provided at an end of portion 66  
15 distal from the conical end portion 60. The stop member 68 is  
16 of a larger outer diameter than the outer diameter of portion  
17 66, as shown. Although the connection of stop member 68 to  
18 portion 66 is shown as threaded, this connection may be made  
19 by any suitable means in the art so as to maintain the  
20 enlarged portion 66 and piston 62 securely on the piston shaft  
21 58. The manner of attaching portion 66 to the piston shaft 58  
22 is by any means which will secure the two together.  
23 Alternatively, the shaft 58 may be formed as a single extruded  
24 piece having separate portions including the conical end 60,

1 enlarged portion 66, and the shaft 58 of desired diameters as  
2 shown. Neither means of formation is preferred and either may  
3 be used according to a manufacturer's selection.

4 Seal grooves 70 are formed in the inner and outer  
5 peripheral surface of the piston member 62 so as to enable  
6 sliding of the piston member 62 along the housing 66 as well  
7 as within the impulse tank portion 46 of the impulse tank  
8 assembly 40.

9 Deflection bumpers 65 are positioned on enlarged portion  
10 66 against an inner end of the enlarged diameter of the stop  
11 member 68 and the inner flat side of the conical end 60. In  
12 FIG. 2, the bumper 63 between the piston 62 and the conical  
13 end 60 is compressed to show the deflection capability of the  
14 deflection bumper 63 when acted upon by a force of the piston  
15 member 62. Likewise, as the piston member 62 slides to the  
16 opposite end of the housing 66, the piston member 62 will  
17 compress the deflection bumper 64 thereat in a similar manner.

18 Once again, when it is desired to fire a device from the  
19 launch tube 44, high pressure air is ported to the tank 46.  
20 This forces the piston 62 within the tank 46 to push water,  
21 which is on the side of the piston adjacent to the launch tube  
22 44, to the breech end of launch tube 44. As this pressure is  
23 higher than sea pressure, a pressure imbalance is created  
24 between the muzzle end and breech end of a device to be

1 launched (not shown) in the launch tube. This results in the  
2 device being ejected from the launch tube. As a submarine  
3 goes deeper under water, the sea pressure on the muzzle of the  
4 launcher becomes greater. Therefore, the high pressure air  
5 source must utilize higher and higher pressure to  
6 satisfactorily effect a launch.

7 The deceleration disks 56 work in conjunction with the  
8 conical end 60 of the piston shaft 58 to restrict fluid flow  
9 from moving from the water side of the piston member 62 to the  
10 launch tube at the end of its power stroke. As the  
11 shaft/piston assembly 58, 62 move toward the end of their  
12 stroke, more and more disks are effectively sealed against  
13 fluid flow by the cylindrical section of the shaft cone 60.  
14 This results in higher and higher pressure being built up on  
15 the water side of the piston member 62. This pressure  
16 counteracts the high air pressure on the air side of the  
17 piston member 62, in an attempt to cushion the last portion of  
18 the piston's travel..

19 Therefore, when the piston assembly comes to its normal  
20 end of stroke, the shaft 58 will continue to travel into the  
21 region where water hammer would normally occur. This will  
22 provide additional time for the deceleration of the water  
23 column which has been forced through the pipe by movement of  
24 the piston 62. This effectively closes the source of the

1 water supply in a more gradual fashion than associated by the  
2 abrupt end of stroke associated with the end of travel of the  
3 piston 62.

4 Referring again to FIG. 2, and in connection with the  
5 reverse travel of the piston stroke, it should also be noted  
6 that the end cap 48 on the high pressure air side of the  
7 assembly includes a cup shaped recess 72 formed therein about  
8 the shaft aperture. The retainer end 68 of the piston/shaft  
9 assembly is received within the recessed cup portion 72 that  
10 the enlarged shaft/retainer assembly does not impede full  
11 travel of the piston 62 within the basic impulse tank 46.

12 FIG. 5 illustrates an alternative embodiment, in which  
13 like reference numbers refer to the like parts of FIG. 2. As  
14 an alternative the deflection bumpers provided in connection  
15 with the housing member 66, it is also possible to utilize a  
16 spring 74 such as a coiled spring on the housing portion 66 of  
17 the piston/shaft assembly to optimize system performance. The  
18 spring 74 is positioned between the inner surface of the  
19 retainer 68 and the air-side surface of the piston member 62.  
20 The spring operates in the same manner as the deflection  
21 bumpers 65.

22 Because of the inventive features of the present  
23 invention, in addition to the piston deceleration control  
24 effected by the deflection bumpers 64 and the deceleration

1 disk dashpot 56, the column of water in the pipe leading to  
2 the launch tube tends to drastically reduce its flow in the  
3 direction of the launch tube. This lessened momentum as  
4 compared to the conventional art removes or substantially  
5 reduces the low pressure area being created in the area of the  
6 launch pipe, closest to the impulse tank 56. This correction  
7 avoids such a rapid stop of flow in the pipeline and thus  
8 eliminates the prior cavitation or water hammer. As a result,  
9 there are no detrimental or readily detectible noise from the  
10 launch of a device from the impulse tank assembly and there  
11 will no longer be a detectable acoustic signature with respect  
12 thereto.

13 Accordingly, the incorporation of the features described  
14 will quiet the launch system such that system shock and  
15 vibration loads and operating noises are reduced. In  
16 addition, the present invention can be easily incorporated  
17 into both new and existing ship systems at a low cost. All  
18 system modifications are internal, integrated into the impulse  
19 tank assembly and are therefore transparent to the system  
20 operator. It is further beneficial and advantageous that  
21 there is no impact on ship arrangement of components.

22 In view of the above detailed description, it is  
23 anticipated that the invention herein will have far reaching  
24 applications other than those of underwater vehicles.

1 This invention has been disclosed in terms of certain  
2 embodiments. It will be apparent that many modifications can  
3 be made to the disclosed apparatus without departing from the  
4 invention. Therefore, it is the intent  
5 to cover all such variations and modifications as come within  
6 the true spirit and scope of this invention.

1 Attorney Docket No. 80018

3

PISTON DECELERATION SYSTEM

4

5

ABSTRACT OF THE DISCLOSURE

6 A piston deceleration system includes an elongated piston  
7 shaft having an intermediate stop member and a second stop  
8 member formed thereon. A piston member is slidably seated on  
9 the elongated shaft between the intermediate stop member and  
10 the second stop member. A tank member is provided having a  
11 first end surface with a first opening and a shaft aperture  
12 formed therein and a second end surface having a second  
13 opening formed therein. The piston shaft is slidably  
14 positioned into the tank member through at least the first end  
15 surface shaft aperture. A shaft shock absorbing member is  
16 positioned between the intermediate stop member and the piston  
17 member on the piston shaft, and a piston shock absorbing  
18 member is positioned between the piston member and the second  
19 end of the tank member.
