TOW CABLE TERMINATION ASSEMBLY

4

5

STATEMENT OF GOVERNMENT INTEREST

6

7

8

9

The invention described herein may be manufactured and used by or for the Government of the United States of America for Governmental purposes without the payment of any royalties thereon or therefor.

10

11

BACKGROUND OF THE INVENTION

12

(1) Field of the Invention

13

14

15

16

17

The present invention relates to a tow cable termination assembly providing the termination and interface between an electro-optical tow cable and a towed array, or other towed optical system, and more particularly to a distributed tow cable termination assembly.

18

(2) Description of the Prior Art

19

20

21

22

23

24

25

Use of a towing cable to tow an array is a well known and acceptable element of a sonar system. The cable typically includes a core of optical fibers and/or electrical conductors housed within a protective jacket. One end of the cable supports the towed system (or array), the opposite end being the strength member termination area. Due to its operating environment, mechanical difficulties have been encountered with

1 prior art towing cables. For example, synthetic fibers having  
2 high strength-to-weight ratios have been used for conventional  
3 tow cable termination assemblies (for example, Kevlar® fiber  
4 available from DuPont, Vectran® fiber available from Hoechst-  
5 Celanese, and Spectra® fiber available from Allied Signal), but  
6 the use of such fibers has not always met with success. In  
7 particular, the design parameters for a conventional tow cable  
8 requires that the synthetic fiber be used as the strength  
9 member, and special lightweight materials be used throughout.  
10 Conventional termination designs provide termination  
11 efficiencies (defined as the ratio of termination break strength  
12 to cable strength) of about 30% to 50% when utilizing these  
13 synthetic fibers. However, the requirements for the next  
14 generation tow cable termination assembly is in excess of 70%.

15 In addition, a second requirement for the termination  
16 assembly is to provide a seal against seawater intrusion into  
17 the core of the cable which can result in failure. Due to the  
18 higher incident of elongation, or stretch, of the fiber strength  
19 member in the tow cable (in comparison to a steel cable),  
20 failures have occurred in the seal area due to incidents of  
21 seawater intrusion. The seawater intrusion primarily results  
22 from the ineffectiveness of current seal designs to prevent  
23 leakage when the fibers become elongated and the core moves  
24 independently of the strength member. Conventional designs  
25 utilize a single o-ring as a secondary seal and do not protect  
26 against seawater intrusion through epoxy injections tubes if the  
27 primary seals fail.

1 Another issue associated with conventional termination  
2 assemblies is that they degrade over time in terms of strength  
3 and seal capability, because of the nature of the synthetic  
4 fibers, and the need to reel the cable around a winch during  
5 use. For example, the forces applied to the termination  
6 assemblies during use can result in a strength loss in the  
7 termination. This has been found to be especially true with  
8 towed array thin line handling systems that use 36" diameter,  
9 multiple groove sheaves for handling the cable. Additionally,  
10 there have been problems associated with breakage of fibers and  
11 wires in the transition area between the tow cable termination  
12 assembly and the towed system. The use of synthetic fiber  
13 increases this problem and has been found to be a very difficult  
14 design issue. The changes in the stiffness between the cable  
15 and the towed system or device can also cause significant damage  
16 to the termination and the cable. The termination assembly is  
17 required to meet all strength and environmental specifications  
18 for their operating life which is expected to be typically about  
19 3-5 years and includes numerous handling and deployment  
20 evolutions. Conventional designs do not support these  
21 requirements.

22 Accordingly, there is needed in the art a tow cable  
23 termination assembly having an improved operating life and which  
24 is cost effective, reliable and easy to manufacture.

SUMMARY OF THE INVENTION

The present invention is directed to a distributed fiber strength member tow cable termination assembly (DTCTA) having a strength member termination area which is spaced from a signal conductor termination area, and further includes a seal area having a plurality of sealing members. The strength member termination area preferably includes a strength member termination wedge having a curved outer face which allows for higher termination efficiency. The strength member termination area and signal conductor termination area are distributed, or separated, by a predetermined distance by, for example a length of hose. In one embodiment, epoxy is fed through holes located inside the primary seal area into the termination wedge. A secondary seal area including a plurality of stacked seals, for example V-cup seals, are also disposed behind the primary seal. The DTCTA further supports all hydrodynamic tow loads applied by the towed system and transfers the data and power over the electro-optical core, as is known in the art.

BRIEF DESCRIPTION OF THE DRAWINGS

It should be understood that the drawings are provided for the purpose of illustration only and are not intended to define the limits of the invention. The foregoing and other objects and advantages of the embodiments described herein will become apparent with reference to the following detailed description when taken in conjunction with the accompanying drawings in which:

1           FIG. 1 is a cross section view of a first end of a strength  
2 member termination area, showing a termination wedge and  
3 secondary redundant seals;

4           FIG. 2 is a cross section view of a middle section of the  
5 strength member termination area, showing the primary and  
6 secondary seals;

7           FIG. 3 is a perspective cross-section view of the tow cable  
8 termination assembly of the present invention; and

9           FIG. 4 is a perspective view of the tow cable termination  
10 assembly of FIG. 3.

11  
12                           DESCRIPTION OF THE PREFERRED EMBODIMENTS

13           Referring now to the Figures, the distributed fiber  
14 strength member tow cable termination assembly (DTCTA) 10  
15 includes a strength member termination area 12, a seal area 14,  
16 and a signal conductor termination area 16. The strength member  
17 termination area 12 supports the towed cable 18 and includes a  
18 strength member termination wedge 20 to minimize the stresses on  
19 the DTCTA during use, as known in the art. The signal conductor  
20 termination area 16, located opposite the strength member  
21 termination area, supports the towed array 22. The seal area 14  
22 supports a primary seal 30 and a plurality of secondary seals  
23 32. In the distributed design of the present embodiment, the  
24 strength member termination area 12 is spaced a predetermined  
25 distance "d" from the signal conductor termination area 16, such  
26 that the signal conductors are not co-located within the  
27 strength member termination area. The separation of the

1 strength member termination area 12 from the signal conductor  
2 termination area 16 allows for several improvements in the DTCTA  
3 not possible in the prior art due to the previous need to  
4 terminate the signal conductors co-located with the strength  
5 termination member. These improvements include, but are not  
6 limited to, a change in geometry in the termination wedge 20  
7 improving termination efficiency; relocation of epoxy injection  
8 tubes 28 to a more beneficial sealing location; provision of the  
9 plurality of secondary redundant seals 32 to improve sealing; a  
10 decrease in length of the strength member and signal conductor  
11 termination members resulting in a reduction in applied forces;  
12 improved bending stiffness; improved handling and termination of  
13 the electro-optical core; and easier manufacture and assembly,  
14 as described in greater detail below.

15 A first improvement of DTCTA 10 is a change in geometry of  
16 the strength member termination wedge 20. The outer surface 22  
17 of the wedge preferable has a slight curvature "c", which allows  
18 the outer surface 22 to better distribute forces over the entire  
19 area of the wedge 20, in the present embodiment. This, in turn,  
20 results in a higher termination efficiency, where the  
21 termination efficiency = termination break strength/cable break  
22 strength. The curvature "c" gives the wedge of the present  
23 invention a different geometry over previous prior art wedges  
24 which included a straight edge outer surface. The separation of  
25 the strength member termination area from the signal conductor  
26 termination area allows the wedge shape to be changed to include  
27 the curved outer surface because of the increased volume in the

1 strength member termination area due to the separation of the  
2 signal conductor termination area. In addition to better  
3 distributing forces, the wedge shape of the present invention  
4 also allows more epoxy into the interior of the wedge because  
5 the wedge member has an increased volume due to its curved  
6 shape. By providing more epoxy in the wedge, the ratio of high  
7 strength fiber to epoxy is decreased, thus also improving the  
8 termination efficiency of the DTCTA by better surrounding and  
9 encapsulating substantially all of the fibers.

10 One or more epoxy injection tubes 28 are preferably placed  
11 within an interior portion 34 of the strength member termination  
12 area such that the tube is interior of both the primary seals 30  
13 and the secondary seals 32. Thus, the injection tubes are  
14 inside of the primary water barrier. By placing the tubes 28 in  
15 this location within the interior portion, and not on the  
16 outside surface of the termination, damage to the primary seal  
17 is isolated and the termination member is protected from  
18 seawater leaking into the epoxy injections tubes 28 and into  
19 wedge 20 which could lead to strength degradation and reduced  
20 operating life. In addition, the epoxy injection tubes are  
21 preferably located such that a first end of the tube is  
22 operatively connected to the base 36, or thickest portion, of  
23 the wedge in the present embodiment. In this location, air  
24 bubbles are readily removed from the wedge as the epoxy enters,  
25 which allows for improved strength and more consistent  
26 termination as the epoxy fills the wedge.

1 Referring now to FIG. 2, the present embodiment further  
2 includes a secondary sealing assembly 33, having a plurality of  
3 secondary redundant seals 32 to improve sealing of the electro-  
4 optical cable core. In the present embodiment, the seals 32 are  
5 "V-cup" type seals which are designed to be utilized with non-  
6 metallic materials, such as cable jackets, as is known in the  
7 art. The "V-cup" design allows for devices which are slightly  
8 non-circular in shape to be reliably sealed. Thus, reliable  
9 sealing is provided during movement of the cable core 15  
10 relative to the strength member area without reduction in the  
11 seal integrity and without seal degradation or damage to the  
12 core. In addition, the seals 32 are preferably stacked, such  
13 that a plurality of redundant seals may be provided. In the  
14 present embodiment six seals are provided, although any number  
15 of seals 32 may be provided, as would be known in the art. It  
16 will be appreciated that should a single seal fail, five backup  
17 seals would remain in place. An adaptor and spring 37 which  
18 supports the seals 32 are also provided as part of the sealing  
19 assembly 33.

20 By separating the strength member termination area 12 from  
21 the signal conductor termination area 16, the length of each  
22 area is shortened as compared to the length of the combined  
23 strength member/signal conductor terminations of the prior art.  
24 In the present embodiment, the length of each area is reduced by  
25 about 20%. When cables are handled (for example, by pulling  
26 through and letting out) a sheave or capstan device is utilized  
27 (not shown), as known in the art. These devices apply forces to

1 the termination that is directly proportional to the termination  
2 length. Thus, by reducing the length of each member by about  
3 20%, a corresponding 20% reduction in the applied forces occurs.  
4 The reduction in applied forces dramatically reduces the  
5 strength loss otherwise suffered by the tow cable termination  
6 assembly 10 over time due to repeated application of the applied  
7 forces during use. In addition, the separation or distributed  
8 design reduces the bending stiffness (or impedance)  
9 discontinuity between the cable and towed system which was  
10 present in the prior art. By adding an additional interface  
11 section 38 between the cable and the towed system, the change in  
12 stiffness between the two is more gradual, thus minimizing the  
13 bend points, and significantly reducing the bending stiffness  
14 discontinuity and degradation which can result. In the present  
15 embodiment, the section 38 may preferably be in the form of a  
16 hose which acts as an interface to allow the bending stiffness  
17 to change more gradually in two increments, rather than one.  
18 The hose may be made of any suitable underwater material, for  
19 example polyurethane and may be connected to the terminations by  
20 fasteners 39, for example radial screws. Alternately, the  
21 section 38 may be made from any suitable material. The electro-  
22 optical cable core is passed through the strength member  
23 termination area and is terminated in the hose interface section  
24 38. In the present embodiment, this allows for up to about 20  
25 feet of transition area for the core termination. With the  
26 additional space provided by the hose assembly section, the  
27 bending and other forces applied to the core and core

1           In addition to the foregoing, by distributing or spacing  
2 the strength member termination area 12 from the signal  
3 conductor termination area 16, assembly of the tow cable  
4 termination assembly is improved. In particular, the various  
5 components of the assembly can be manifested and assembled  
6 independently which reduces the complexity and cost for assembly  
7 of the cable termination assembly.

8           It will be understood that many additional changes in the  
9 details, materials, steps and arrangements of parts, which have  
10 been herein described and illustrated in order to explain the  
11 nature of the invention, may be made by those skilled in the art  
12 within the principle and scope of the invention as expressed in  
13 the appended claims.

TOW CABLE TERMINATION ASSEMBLY

4

5

ABSTRACT OF THE DISCLOSURE

6

7 A distributed fiber strength member tow cable termination  
8 assembly (DTCTA) having a strength member termination area which  
9 is spaced from a signal conductor termination area, and which  
10 includes a seal area having a plurality of sealing members is  
11 disclosed. The strength member termination area preferably  
12 includes a strength member termination wedge having a curved  
13 outer face which allows for higher termination efficiency. The  
14 strength member termination area and signal conductor  
15 termination area are distributed, or separated, a predetermined  
16 distance by an interface section, for example a length of hose.  
17 The separation of the strength member termination area from the  
18 signal conductor termination area allows for several  
19 improvements in the DTCTA not possible in the prior art due to  
20 the previous need to terminate the signal conductors co-located  
with the strength termination member.
