15

16

17

18

(2) Description of the Prior Art

19

20

21

22

23

24

25

Clearing underwater mines is a complicated, costly endeavor. The per-mine-killed cost of a robust system is often much greater than the cost of each mine. This unbalance is unacceptable since mass produced underwater mines could limit a navy's ability to operate in vast near-shore areas. The state of the art in mine clearance has relied on using sophisticated unmanned underwater vehicles (UUVs) each having a single warhead. The state of the

1 art UUV locates an underwater mine, maneuvers in close proximity
2 to it, and detonates the warhead. The underwater explosion is
3 successful in the neutralization of a single mine if the UUV is
4 positioned correctly. However, there are several shortcomings to
5 this state of the art approach. The use of an underwater
6 explosion precludes any element of stealth in the clearance of a
7 single mine. This can be a major tactical shortcoming of the
8 current methodology. Another is that the effectiveness of this
9 technique relies on very accurate placement of the detonating
10 charge to at least close proximity to the mine. Consequently,
11 attaining this proximity comes at the considerable cost of a
12 complex targeting system, complex vehicle control systems, and a
13 complex vehicle to house such systems.

14 Furthermore, the contemporary UUV is often guided by
15 communication links to a surface or underwater platform and
16 requires significant involvement of crew resources to manage the
17 launching, targeting and recovery of the UUV. The time to clear
18 a well-mined area can be excessive and during the mine clearing
19 operation, the naval assets managing and in support of the task
20 may be easily targeted. The fact that simple floating mines may
21 be mass-produced a very low cost produces yet another severe
22 obstacle for an expensive system that can clear only a single
23 mine. The problems associated with targeting mines in shallow
24 water are also a concern, for examples, poor acoustics and water
25 clarity limit traditional targeting systems.

1 Another object of the invention is to provide a system
2 having the capability to neutralize several underwater mines with
3 a single system during a single mission.

4 Another object of the invention is to provide a method and
5 apparatus to tag and target mines quickly over a wide area.

6 Another object is to provide a method and apparatus to tag a
7 plurality of mines from a single airborne platform.

8 Another object is to provide a method and apparatus to tag
9 mines in a covert fashion.

10 Another object is to provide a method and apparatus is to
11 tag mines for a finite duration of time.

12 Another object of the invention is to provide a method and
13 apparatus to quickly identify tagged underwater mines.

14 Another object of the invention is to provide a method and
15 apparatus for the rapid destruction of tagged mines.

16 Another object is to provide a method and apparatus to
17 destroy a number of mines in a covert fashion by a single UUV
18 platform.

19 Another object is to provide a cost effective means to
20 destroy mines from long range.

21 Another object of the invention is to provide a mine
22 clearance platform that may operate in its own self-defense.

23 Another object of the invention is to provide a method and
24 apparatus to destroy underwater mines located at different depths
25 in the water.

1 Another object is to provide a mine clearance system that
2 may operate autonomously or with operator control.

3 Another object is to provide means to identify more mines
4 than existing systems do.

5 These and other objects of the invention will become more
6 readily apparent from the ensuing specification when taken in
7 conjunction with the appended claims.

8 Accordingly, the present invention is a method and apparatus
9 to clear mines underwater. Tag particles are dropped from an
10 aircraft over a wide area of the ocean to sink and stick on
11 submerged mines. An unmanned underwater vehicle (UUV) platform
12 locates and neutralizes mines that have tag particles on them.
13 The platform has an elongate cylindrical-shaped pressure hull
14 that could be launched from a torpedo tube, for example. The tag
15 particles each contain a gas volume dimensioned to resonate with
16 impinging acoustic energy and create reflected portions of the
17 impinging acoustic energy from a targeted mine. The UUV platform
18 has a sonar system provided with at least one transducer to
19 project the acoustic energy through the ambient water. At least
20 one hydrophone transducer in the sonar system receives the
21 reflected portions of the projected acoustic energy to locate a
22 targeted mine to enable its destruction by high-energy
23 supercavitating projectiles fired from the UUV platform. All tag
24 particles dissolve after a period of time to provide no
25 discernable traces of a mine hunting operation.

1 BRIEF DESCRIPTION OF THE DRAWINGS

2 A more complete understanding of the invention and many of
3 the attendant advantages thereto will be readily appreciated as
4 the same becomes better understood by reference to the following
5 detailed description when considered in conjunction with the
6 accompanying drawings wherein like reference numerals refer to
7 like parts and wherein:

8 FIG. 1 is a schematic view of the mine clearance system of
9 this invention;

10 FIG. 2 is a schematic view showing details of the UUV;

11 FIG. 3A schematically shows a tag particle while it is dry
12 before deployment in water;

13 FIG. 3B schematically shows a tag particle when it is wetted
14 at a time $t=0$ as it is dropped into water;

15 FIG. 3C schematically shows a tag particle after a time past
16 time $t=0$ upon dissolution of a water soluble acoustically
17 transparent cover and adhesive; and

18 FIG. 4 schematically depicts the UUV platform engaging a
19 tagged mine.
20

21 DESCRIPTION OF THE PREFERRED EMBODIMENTS

22 Referring to FIGS. 1 and 2 of the drawings, mine clearance
23 system 10 has an unmanned underwater vehicle (UUV) platform 20
24 deployed from a remote site 11. UUV platform 20 operates in
25 concert with tag particles 40 to neutralize targets, such as a

1 mine 50 or field of mines beneath the surface of water 60. Mines
2 typically are buoyant and are held in place by a tether 50A. UUV
3 platform 20 and tag particles 40 of mine clearance system 10
4 synergistically cooperate to improve kill ratios of mines 50 as
5 compared to more costly, contemporary systems.

6 FIG. 1 shows an aircraft 70 dropping of tag particles 40 and
7 UUV platform 20 positioned in water 60. It is to be understood,
8 however, that tag particles 40 of this invention are more likely
9 to be dropped from or sown by aircraft 70 across a wide area, or
10 region suspected of being mined prior to deployment of UUV
11 platform 20. Aircraft 70 may be a conventional fixed wing
12 aircraft, drone aircraft, or helicopters. Surface vessels may be
13 used to disperse tag particles 40. Some particle disbursement
14 methods may be more desirable than others for avoiding unwanted
15 attention.

16 UUV platform 20 can have an elongate cylindrical-shaped
17 pressure hull 21 enabling its launch from a tube, such as a
18 torpedo tube at remote site 11. Hull 21 is made from metal or
19 synthetic materials having sufficient strength for bearing
20 ambient water pressure. Other components to be described herein
21 also are substantially built and sealed to reduce the effects of
22 ambient water pressure, and these components and interconnections
23 are made according to acceptable and established marine
24 engineering principles for successful operation while UUV
25 platform 20 hunts and destroys mines 50 at depths.

1 At least one propeller 22 can be located aft on hull 21 and
2 is connected to an appropriate motor and power supply (not shown)
3 to propel UUV platform 20. The power supply can additionally be
4 used to power communication, sensor, processing, and activation
5 modules in UUV platform 20. An optical fiber 23 can be deployed
6 from a spool of such fiber in hull 21 to extend from an extension
7 23A of UUV platform 20 to remote site 11. Optical fiber 23 will
8 function as an optical communication link. This link will
9 transmit control signals to UUV platform 20 from remote site 11
10 and data signals from UUV platform 20 to remote site 11.

11 UUV platform 20 has modular systems on board to assure
12 responsive buoyancy and propulsion, auto pilot and guidance
13 including optical, acoustic and other navigation systems as well
14 as Global Positioning System (GPS) compatible systems. Such
15 systems are well established in the art and can be selected and
16 tailored for incorporation into UUV platform 20 by one skilled in
17 the art. UUV platform 20 additionally has an acoustic sensor
18 system, or sonar system 24 schematically depicted as being
19 located near the nose portion of UUV platform 20. As shown in
20 FIG. 4, this system has at least one acoustic transducer to
21 project acoustic energy 24A through ambient water 60 and at least
22 one acoustic transducer (hydrophone) to receive reflected
23 portions 24B of the projected acoustic energy from mines 50.
24 Acoustic energy 24A can be projected in response to control
25 signals sent over optical fiber 23 from remote site 11, and the

1 information concerning the reflected acoustic energy 24B can be
2 transmitted over optical fiber 23 to site 11.

3 The acoustic transducers project and receive acoustic energy
4 at high frequencies to provide meaningful imaging from reflected
5 acoustic energy from the tag particles on the mines 50 to
6 identify the mines. The high frequencies of the projected and
7 reflected acoustic energy 24A and 24B may typically be in the
8 range, for example, from between 100 KHZ and 2 MHZ for acceptable
9 resolution. These typical frequencies of sonar system 24, are
10 intended to be exemplary and not intended to be limiting, and
11 this energy is used to detect tag particles 40 as explained
12 below.

13 UUV platform 20 has two underwater projectile systems 25A
14 and 25B. Projectile systems 25A and 25B fire supercavitating
15 projectiles 25C (FIG. 4). Supercavitating projectiles 25C may be
16 bullet-like missiles propelled from conventional cartridges by
17 detonating propellants or may be rocket-like projectiles
18 propelled by exhaust gases produced from burning rocket
19 propellants from launch rack-like structure in UUV platform 20.
20 In either case, projectiles 25C are designed to be
21 supercavitating assuring sufficiently high velocity passage
22 through the water and sufficient kinetic energy to destroy or
23 otherwise neutralize a targeted mine 50.

24 Projectile system 25A is oriented to shoot supercavitating
25 projectiles 25C into its targeted mine 50 when the designated

1 mine 50 is directly in front of, or aligned with the longitudinal
2 axis of UUV platform 20. Projectile system 25B is oriented to
3 shoot supercavitating projectiles 25C into its targeted mine 50
4 when the designated mine 50 is at right angles to the
5 longitudinal axis of UUV platform 20. Projectile systems 25A and
6 25B may have magazines of supercavitating projectiles 25C fired
7 from firearm-like cartridges or launched from stacked rocket
8 launching racks so that systems 25A and 25B are therefore,
9 capable of firing multiple rounds in bursts or as single shots.
10 Bursts of supercavitating projectiles, such as shown in FIG. 4
11 might be used to facilitate the destruction of not only mines 50
12 but also moving targets, such as a threatening hostile undersea
13 craft or incoming missiles. In addition, firing bursts of
14 projectiles 25C from projectile systems 25A and 25B may help
15 reduce the necessity of having an elegant targeting solution.

16 A flash-suppressing muzzle can be provided for projectile
17 systems 25A and 25B to reduce the possibility of detection of
18 their firing. Projectile systems 25A and 25B can also have
19 laser-targeting systems (not shown) that may include a laser
20 designator aligned with projectile systems 25A and/or 25B to
21 illuminate a target. In addition laser-targeting systems for
22 systems 25A and 25B could be responsive to laser designation from
23 another UUV platform that has a laser designator to kill an
24 illuminated mine 50.

1 UUV platform 20 may additionally be provided with a magnetic
2 detection and fuzing device 26 that can use magnetic sensing and
3 homing to detect mine 50 and aim and align underwater projectile
4 systems 25A and 25B for destruction of the targeted mine 50.
5 Device 26 might additionally be used to identify and home in on
6 threatening countermeasures or hidden magnetic objects that
7 otherwise might not be discovered.

8 UUV platform 20 is stabilized for steering, station keeping,
9 and accurate firing of supercavitating projectiles 25C from
10 projectile systems 25A and 25B by pop-out wings 27 and control
11 surfaces 29. Pop-out wings 27 are pivotally rotated from slot-
12 shaped bays 28 in UUV platform 20. Fore, or aft fin-like control
13 surfaces 29 are outwardly displaced from UUV platform 20 to a
14 fixed position after launch from the tube at remote site 11.
15 Wings 27 and control surfaces 29 may be selectably rotated by
16 suitable mechanisms responsive to control signals for steering
17 and maintaining the attitude of UUV platform during transit to
18 mine 50 and/or during firing of projectiles 25C. Wings 27 and
19 control surfaces 28 may also have controllable flaps to further
20 refine control.

21 Maneuvering and stabilizing UUV platform 20, particularly
22 during firing, can further be augmented by a vectored thrust
23 control system 30. Vectored thrust control system 30 has a
24 number of radially outwardly pointing nozzles 30a that direct
25 selective high pressure flows of fluid outwardly to hold UUV

1 platform 20 steady and allow firing of projectiles 25C at
2 targeted mines 50, or other targets, at any orientation.

3 An underwater camera system 31 is used to assist transit to
4 the targeted mines and to assist in the final targeting of mines
5 50. Camera system 31 is mounted forward on UUV platform 20 and
6 may have a source of visible or non-visible radiation, depending
7 on the type of camera used. During progression to a targeted
8 mine 50, the radiation source can radiate energy on not only the
9 area in front of UUV platform 20 but also marine topography at
10 the bottom of ambient water 60. The high level of radiation
11 enables a sensor package, e.g., camera, radiation detector, etc.,
12 in camera system 31 to receive reflected portions of the
13 radiation and provide data signals representative of ambient
14 features and mines 50. These data signals are processed in
15 processing, logic, and relay modules in UUV platform 20 and
16 relayed remote site 11. UUV platform 20, therefore, has another
17 capability for avoiding obstacles, following a series of known
18 undersea features and/or locating and identifying mine 50.
19 Because UUV platform 20 may be submerged to a considerable depth
20 in water 60, the radiation associated with camera system 31 is
21 hidden from possibly unfriendly observers above water 60 as data
22 is gathered.

23 A conventional warhead 32 can be included in UUV platform 20
24 to destroy a high value target or hardened target. Warhead 32

1 might also be detonated to destroy or scuttle UUV platform 20
2 when such action is desired.

3 Responsive displacements of propeller 22, wings 27 control
4 surfaces 28 and vectored control system 30 via modules in UUV
5 platform 20 steer and guide UUV platform 20 to the vicinity of
6 one or more mines 50. The processing and logic modules for
7 accomplishing this are well known in the art and are included in
8 UUV platform 20 where they process incoming data signals from
9 sonar system 24 and camera system 31. Furthermore, the
10 processing, logic and transceiver modules in UUV platform 20 are
11 also responsive to command signals received from remote site 11
12 over optical fiber 23. These modules can be responsive to
13 acoustic command signals received through ambient water 60 from
14 remote site 11 by the hydrophone transducers of sonar system 24.
15 Accordingly, these modules create internal control signals for
16 maneuvering UUV platform 20 in response to data signals and the
17 remotely originating command signals thereby steering and
18 guiding UUV platform 20 to mine 50. Thus, UUV platform may be
19 deployed at remote site 11 and may travel a distance of several
20 nautical miles underwater under the control of command signals
21 from remote site 11. Once near mine 50, UUV platform 20 may rely
22 on data signals from sonar system 24, magnetic system 26, and
23 camera system 31 to acquire, identify, and home in on one or more
24 mines 50 and destroy them by projectile systems 25A and 25B.

1 Mine clearance system 10 of this invention has tag particles
2 40 to aid in locating, identifying, and destroying mines 50.
3 Referring to FIGS 3A, 3B, and 3C, each tag particle 40 has a
4 virtually uniformly sized volume of gas 41 contained inside a
5 water-soluble acoustically transparent cover 42 that is at least
6 partially coated by a water-activated adhesive 43. Each
7 acoustically transparent cover 42 allows interaction between
8 impinging acoustic energy from projector-transducers of sonar
9 system 24 and each gas volume 41. The uniform size of gas
10 volumes 42 and the relatively great acoustic impedance between
11 the gas and the surrounding water will make each tag particle 40
12 resonate, or appear to radiate as a dominant acoustic source as
13 compared to the ambient. This resonance, or apparent radiation
14 will be created when each tag particle 40 is exposed to projected
15 acoustic energy from transducers 24 at the particle's resonant
16 frequency. The resonant frequency is a function of the
17 dimensions of the gas volume 41 in the particle 40. Optionally,
18 the projected acoustic energy could come from another source,
19 such as remote site, for example. Consequently, each mine 50
20 that has tag particles 40 on it will become more acoustically
21 enhanced, or prominent in the projected acoustic energy from
22 sonar system 24. This will enable location of tagged mines 50 at
23 greater distances than untagged mines 50.

24 Referring also to FIG. 3A, when tag particles 40 are being
25 stored or transported while they are in the dry state, or dry,

1 the outer water-activated adhesive 43 is inert preventing
2 coalescence of tag particles 40. Accordingly, tag particles 40
3 can be stored in mass quantities on board aircraft 70 and freely
4 sown or dropped to disperse over a wide area or region where
5 mines 50 are suspected of being located. The combined weight of
6 gas volume 41, cover 42, and adhesive 43 of each tag particle 40
7 is such as to make tag particles 40 be negatively buoyant and
8 sink when they are in water.

9 Referring also to FIG. 3B, when adhesive 43 of each tag
10 particle 40 contacts water 60 at a time, $t = 0$, it is wetted and
11 becomes activated (sticky). The outer, wetted surfaces of
12 adhesive 43 become sticky enough to adhere to the outer surfaces
13 of mines 50. The gas volume 41 can be air, nitrogen or any type
14 of relatively non-reactive gas having low moisture content.
15 Cover 42 can be gelatin or some other acoustically transparent
16 water-soluble material. Adhesive 43 can be any well-known water
17 activated adhesive.

18 Referring also to FIG. 3C, after a period of time in water
19 60 beyond $t = 0$, adhesive 43 dissolves, and water-soluble cover
20 42 dissolves. The dissolving of adhesive 43 and cover 42 of each
21 tag particle 40 frees gas volume 41 to the water where it may
22 escape. Consequently, there are virtually no readily discernable
23 traces of tag particles 40 left for detection of the tagging
24 process. Selection among well-known materials for and tailoring

1 of cover 42 and adhesive 43 by one skilled in the art can change
2 the rates of activation and dissolution.

3 Referring also to FIG. 1, aircraft 70 carrying dry tag
4 particles 40 flies over a suspected minefield and drops tag
5 particles 40 across a wide area of water 60. Since tag particles
6 40 are heavier than water 60, they sink in water 60 as tag
7 particles 40, designated 40AA. Water 60 activates adhesives 43
8 on cover 42 causing particles 40AA to become sticky. A small
9 number of tag particles 40, designated 40BB, are stuck on the
10 outer surfaces of mines 50. The remainder of tag particles 40
11 settle on the bottom of water 60 and are designated 40CC. UUV
12 platform 20 searches for reflected acoustic energy from mines 50,
13 those mines 50 that are tagged with adhered tag particles 40
14 (40BB) can be detected and UUV platform 20 can home in on them.
15 Tag particles 40 (40CC) at the bottom are not detected, and after
16 a period of time, they will dissolve sufficiently to each release
17 gas volume 41 which is buoyed to the surface of water 60.

18 Referring to FIG. 4, UUV platform 20 detects a tagged mine
19 with projected and reflected acoustic energy at enhanced ranges
20 for subsequent visual identification by camera system 31. Tag
21 particles 40BB of mine hunting system 10 that are adhered to
22 mines 50 make the job of finding them by UUV platform 20 easier
23 and at a greater distance as compared to contemporary systems.
24 After location and identification, each mine 50 can be
25 methodically destroyed by UUV platform 20 which aims and fires

1 one or more aimed high-kinetic energy supercavitating projectiles
2 25C. The aimed high-energy supercavitating projectiles 25C from
3 projectile systems 25A and 25B are fired, or launched from UUV
4 platform 20 that is located at a safe separation distance from
5 each mine 50. The use of a supercavitating projectile 25C
6 greatly extends the offset, or separation distance at which it
7 will penetrate each mine 50. The penetration of each mine 50
8 underwater with high kinetic energy supercavitating projectile
9 25C completes the neutralization of each mine 50, and the safe
10 separation distance reduces the possibility of damaging UUV
11 platform 20 so that it can find and destroy a number of mines
12 during a single deployment.

13 Mine clearance system 10 of the invention uses
14 supercavitating projectiles 25C fired from underwater projectile
15 system 25A and 25B on UUV platform 20 to destroy mines 50
16 underwater. Mine clearance system 10 also can use its
17 supercavitating projectiles 25C from projectile systems 25A and
18 25B for self-defense. Mine clearance system 10 has the ability
19 to place tag particles 40 on mines 50 across a wide area or
20 region via one or more aircraft 70 and deploy more than one UUV
21 platform 20 to simultaneously clear mines 50 from an area.

22 Mine clearance system 10 uses tag particles 40 designed to
23 "tag" underwater mines 50 and then dissolve and dissipate their
24 gas volumes to limit their lifetime. Mine clearance system 10
25 uses identifying tag particles 40 to locate mines by acoustic

1 means by its sonar system 24, and optionally may use magnetic
2 device 26 and/or camera system 30.

3 Mine clearance system 10 of this invention provides for (1)
4 less cost per mine destroyed, and (2) destruction of a large
5 number of mines per mission as compared to contemporary mine
6 neutralization systems. Mine clearance system 10 additionally
7 has the ability to: (1) target and locate more mines per mission,
8 (2) target mines quicker, (3) destroy mines in more adverse
9 environmental conditions, (4) destroy mines from greater
10 distances, (5) destroy mines undetected, (6) destroy mines
11 located over a wider range of depths, and (7) destroy mobile
12 mines as compared to contemporary mine neutralization systems.

13 The disclosed components and their arrangements as disclosed
14 herein all contribute to the novel features of this invention.
15 Mine clearance system 10 of this invention provides a reliable
16 and cost-effective means to remove the threat that may otherwise
17 be created by underwater mines. Therefore, mine clearance system
18 10 as disclosed herein is not to be construed as limiting, but
19 rather, is intended to be demonstrative of this inventive
20 concept.

21 It will be understood that many additional changes in the
22 details, materials, steps and arrangement of parts, which have
23 been herein described and illustrated in order to explain the
24 nature of the invention, may be made by those skilled in the art

- 1 within the principle and scope of the invention as expressed in
- 2 the appended claims.

2

3

LOW COST RAPID MINE CLEARANCE SYSTEM

4

5

ABSTRACT OF THE DISCLOSURE

6 A method and apparatus to clear mines uses tag particles
7 dropped into ambient water across a wide area by an aircraft to
8 sink and stick to submerged mines. The tag particles each
9 contain a gas volume dimensioned to resonate with impinging
10 acoustic energy and reflect portions of the impinging acoustic
11 energy from a targeted mine. An unmanned underwater vehicle
12 platform having a sonar system provided with at least one
13 transducer projects the acoustic energy through the ambient
14 water. At least one hydrophone transducer in the sonar system
15 receives the reflected portions of the projected acoustic energy
16 to locate a targeted mine to enable its destruction by high-
17 energy supercavitating projectiles fired from the platform. Tag
18 particles dissolve after a period of time to provide virtually no
19 discernable traces of a mine hunting operation.
