DRAG COEFFICIENTS  
FOR  
IRREGULAR FRAGMENTS

by

Frank McCleskey

Naval Surface Weapons Center  
Dahlgren, Virginia 22448

Autovon 249-7993  
Commercial 703-663-7993

The Naval Surface Weapons Center (NSWC) has a continuing task from the Department of Defense Explosive Safety Board (DDESB) to establish methods for predicting the fragment hazards due to the inadvertent explosion of ordnance items. As part of this task, NSWC has established a computer model which predicts fragment hazards. This computer model was explained in the minutes of the twenty-first DCD Explosives Seminar.

The computer model calculates individual trajectories for each fragment recovered in small-scale fragment arena tests. The following variables affect the individual fragment trajectories:

- EI - Initial Elevation Angle
- VI - Initial Velocity
- A/M - Area to Mass Ratio
- ALT - Altitude
- RHO - Air Density
- MN - Mach Number
- HO - Height of the Origin
- SC - Soil Constant (Ricochet)
- W - Wind Speed and Direction
- $C_D$  - Drag Coefficient

Except for  $C_D$ , all of these variables can be defined with a fair degree of accuracy by tests, measurements, and calculations.

The drag coefficient for any fragment is a function of shape only. For regular fragments, like spheres or cubes, the drag coefficients are reasonably well defined. For irregular fragments, like those from bombs or concrete walls, no two fragments have exactly the same shape. As a result, no two irregular fragments have exactly the same drag coefficient. In all cases, drag coefficient is a function of Mach Number.

The drag coefficients for irregular fragments are not only uncertain but have a pronounced effect on far-field range. Figure 1 shows range versus  $C_D$  for a typical fragment. The range of low subsonic  $C_D$  varies from .5 to 1.5, a factor of three. Associated range varies by a factor of more than 2. This represents a large range uncertainty in trajectory calculations for establishing fragment hazards. If this uncertainty is to be reduced, some correlation must be established between  $C_D$  and the characteristics of the irregular fragments.

$C_D$  is a function of shape only. Therefore any correlating parameter should be dimensionless; that is, geometrically similar fragments which have the same  $C_D$  should have the same correlating parameter. For example, we might take the ratio of the maximum presented area to the minimum presented area as a measure of shape. For a sphere this ratio would always be one no matter what the size of the sphere. For a cube this ratio would always be 1.732.

The impetus for this program was provided by an observation having to do with the data contained in reference (a). That report contained the first systematic look at air drag for fragments. Three regular fragments were studied in the report, i.e., a sphere, a cube and a bar. The bar length,

width and thickness were in the ratio of 5-1-1. Since these fragments were regular, exact ratios of maximum to minimum presented area could be calculated. The results were as follows:

	FRAGMENT SHAPE		
	SPHERE	CUBE	BAR (5-1-1)
$C_D$ (MN .75)	.60	.88	1.12
$A_{MAX}/A_{MIN}$	1.00	1.73	7.14

Note that as the correlation ratio increases so does the  $C_D$ . The report also showed that the  $C_D$  for irregular fragments was greater than those for the sphere or cube. For irregular fragments the area ratio could be expected to be on the order of that for the bar. Everything seemed to support the idea that the  $C_D$  for irregular fragments could be correlated with dimensionless parameters.

To follow up on this idea, it was decided to choose 96 fragments with a wide variation of shapes for test in the vertical wind tunnel at Ballistic Research Laboratory (BRL) in Aberdeen, Maryland. Four different kinds of measurement were made on each fragment.

1. Linear Maxima: Length, width and thickness
2. Linear Averages: Length, width and thickness
3. Perimeters: (3 planes)
4. Presented Areas
  - a. Maximum
  - b. Average
  - c. Minimum
  - d. Variance
  - e. Standard Deviation

Linear dimensions were measured as shown in Figure 2. Note that in calculating average dimensions, the average thickness is calculated to produce an equivalent weight and volume rectangular parallelepiped.

Perimeters were measured in three planes as shown in Figure 3. Note that the perimeters do not exactly follow the contour of the fragment but represent a stretched string around the high points.

Fragment presented areas were measured in two ways. Measurements were made using an icosahedron gage, and calculations were performed on the equivalent weight and volume rectangular parallelepipeds. Figures 4 and 5 show the essentials of these measurements and calculations. The icosahedron gage is an optical device which throws a shadow of the fragment onto a sensing surface. The associated electronics produces a readout of presented area. The optical axis is positioned at 16 approximately equally spaced aspects so as to produce 16 distinct presented areas which can be analysed for a variety

of statistics. The icosahedron gage cannot mount a fragment weighing more than 1500 grains. For larger fragments, presented area statistics are calculated using the rectangular parallelepipeds as shown in Figure 5.

All of the linear, perimeter and area measurements for the 96 fragments are contained in Tables A-1, A-2 and A-3 of Appendix A.

The essential aspects of the vertical wind tunnel are shown in Figure 6. In operation, a fragment is placed on the fragment support screen in either the upper or lower test section depending on the air velocity necessary to raise the fragment. The air speed is controlled by opening the inlet vanes of the constant speed fan. The air speed is adjusted until the fragment rises from the screen and assumes a relatively constant height. At this time, the air stream velocity is read directly from the velocity calibrated manometer. Air density is calculated from the ambient pressure and temperature. Ambient conditions are acceptable because of the relatively low air velocities produced in the tunnel. These parameters together with the weight and average presented area of the fragment are then used to calculate the low subsonic drag coefficient ( $C_D$ ).

Each fragment was tested in the vertical wind tunnel. The velocity of the air stream is increased until the fragment hovers in the air stream at near constant vertical height. In this vertical equilibrium position the drag and gravity forces will also be in equilibrium. From previous measurements we know the weight and average presented area of the fragment. From the wind tunnel we establish the density and velocity of the air stream. As shown in Figure 7, once we know these values, we can calculate  $C_D$ . Since we operate at a single air velocity we can only obtain a single point on the drag curve. This point is in the low subsonic region, roughly about a Mach Number of 0.1. The remainder of the drag curve must be inferred from other sources.

Three regular fragments (sphere, cube and bar) which were tested in reference (a) were also tested in the vertical wind tunnel. In reference (a) however,  $C_D$  was obtained at a Mach Number of approximately .75. The results were as follows:

	$C_D$ Wind Tunnel	$C_D$ Reference (a)	Delta
Sphere	.42	.60	+ .18
Cube	.64	.88	+ .24
Bar	.94	1.12	+ .18

As seen in the table,  $C_D$  at Mach .75 is about .2 higher than  $C_D$  at Mach .1 for all three fragments. Owing to the consistency in the rise of  $C_D$  from Mach .1 to Mach .75 for the three regular fragments, it seems reasonable at this time to accept the same rise in  $C_D$  for irregular fragments. In this way, the shape of the subsonic drag curve (as a function of Mach Number) for irregular fragments is established.

Experience shows that range is more sensitive to changes in subsonic  $C_D$  than to similar changes in supersonic  $C_D$ . This can best be seen in Figures 8 and 9. The shape of the transonic and supersonic portions of the drag curves in Figure 8 are approximations based on the study of scattered data in

reference (a) and (b). On the left side of Figure 8, the subsonic  $C_D$  is held constant while the supersonic  $C_D$  is allowed to vary  $\pm 25$  about the mean. The range differences from the mean are both less than 100 feet. On the right side of Figure 8, the supersonic  $C_D$  is kept about the same as before and the subsonic  $C_D$  is allowed to vary  $\pm 25$  about the mean. If subsonic and supersonic  $C_D$  were equally sensitive then the new range differences (deltas) should be about twice what they were before. In fact, they are about four times as large.

This range sensitivity can be further explained by the data in Figure 9 where velocity is plotted against range ratio for a typical far-field trajectory. The range ratio is the fraction of the total trajectory traversed. From the figure it can be seen that only 25 percent of the trajectory is supersonic while 75 percent is subsonic. Figures 8 and 9 demonstrate that the subsonic portion of the drag curve affects range much more than the supersonic portion.

Tables A-4, A-5 and A-6 of Appendix A list all of the dimensionless ratios considered to date. When plots of  $C_D$  versus the ratios were made, the best correlation was obtained with the ratio  $A_{MAX}/A_{AVG}$ ; that is, the ratio of the maximum presented area to the average presented area. This correlation is shown on Figure 10. The value for  $A_{MAX}/A_{AVG}$  is an average of the values obtained using the icosahedron gage and the equivalent rectangular parallelepiped calculations. The total range of uncertainty for all irregular fragments is from about 0.5 to 1.5. The range of  $C_D$  uncertainty at an average  $A_{MAX}/A_{AVG}$  of 1.45 to 1.5 is about 0.6. On average then, it can be said that the correlation reduces the uncertainty by about 40 percent.

It is important to know what a 40 percent reduction in  $C_D$  uncertainty means in terms of range uncertainty. Figure 11 shows this range uncertainty for a typical fragment trajectory with a presented area ratio of 1.5. The range differences are large, about 18 percent above the average and 28 percent below. In order to reduce the range uncertainty to an acceptable region of about  $\pm 10$  percent, it will be necessary to reduce the  $C_D$  uncertainty by about 75 percent.

In summary, the following observations can be made:

1.  $C_D$  is a function of shape only.
2. Range is more sensitive to subsonic than to supersonic  $C_D$  variations.
3.  $C_D$  correlates with dimensionless parameters.
4. The  $A_{MAX}/A_{AVG}$  parameter correlation reduces  $C_D$  uncertainty by approximately 40 percent.

Significant problems remain unresolved. For an acceptable range uncertainty of about  $\pm 10$  percent, it will be necessary to reduce the  $C_D$  uncertainty by about 75 percent. This might be done in a variety of ways. More efficient correlation parameters might be established. The typical motion of the fragments in the wind tunnel (Figure A-1 thru A-9 of Appendix A) might be used as an added correlation. Possibly, the use of presented area

other than average might be used in calculating  $C_D$ . For example, in Figure A-3 of Appendix A all fragments exhibit a flat rotation such that the area presented to the air stream is much greater than the average presented area.

Another unresolved problem involves the shape of the transonic and supersonic portions of the drag curve. At present, the shape is only an approximation based on scattered data contained in references (a) and (b). A practical method is needed to test irregular fragments for  $C_D$  in a supersonic wind tunnel. The essential problem is the design of a fixture which will allow the fragment to move freely and, at the same time, continually measure drag force.

**APPENDIX A**

**1566**

This Appendix contains 6 Tables and 9 Figures.

Table A-1 contains 16 presented areas measured by the icosahedron gage for the 84 fragments which could be mounted on the gage. Table A-2 presents the linear and perimeter measurements for all 96 fragments. LWP, LTP and TWP are the perimeter measurements in the LW, LT and TW planes, respectively. Table A-2 also contains the subsonic ( $M = 0.1$ )  $C_D$  measured for each fragment in the vertical wind tunnel. Table A-3 contains the presented area measurements for the 96 fragments obtained from the icosahedron gage and calculations using the equivalent rectangular parallelepipeds. Tables A-4, A-5 and A-6 contain the dimensionless ratios which were investigated as correlation parameters for  $C_D$ . Note that the fragments have been reordered in ascending  $C_D$  to help in the  $C_D$  correlation. The old frag number is that designated in Tables A-1, A-2 and A-3.

During the wind tunnel testing, the motion of each fragment was recorded. It was found that the motions could be defined in 9 distinct types. Each figure shows the plan views (L-W plane) of those fragments exhibiting the distinct motion indicated on the figure. Two numbers are given below each fragment. The first is the fragment number contained in Tables A-1, A-2 and A-3. The second number, in parenthesis, is the subsonic  $C_D$  measured in the vertical wind tunnel. It was hoped that knowing the shape, motion and  $C_D$  might provide an additional method for correlation. Currently, this has not been realized. It is interesting to note that only 35 percent of the fragments tumble randomly. This is at odds with the traditional assumption that all fragments tumble randomly in flight. It is because of the traditional assumption that  $C_D$  is calculated using the average presented area.

EXPLANATION OF COLUMN HEADINGS  
 MIN AREA - MINIMUM PRESENTED AREA (SQ. IN.)  
 MAX AREA - MAXIMUM PRESENTED AREA (SQ. IN.)  
 AVG AREA - AVERAGE PRESENTED AREA (SQ. IN.)  
 STD DEV - STANDARD DEVIATION OF PRESENTED AREA (SQ. IN.)  
 VARIANCE - VARIANCE OF PRESENTED AREA (IN. 4TH)  
 ICOS - AREAS CALCULATED FROM ICOSAHEDRON GAGE DATA  
 CALC - AREAS CALCULATED FROM APPROXIMATING RECTANGULAR PARALLELEPIPEDS

HEADINGS

L - AVERAGE LENGTH      W - AVERAGE WIDTH      T - AVERAGE THICKNESS

L' - MAXIMUM LENGTH PLUS AVERAGE LENGTH

W' - MAXIMUM WIDTH PLUS AVERAGE WIDTH

T' - MAXIMUM THICKNESS PLUS AVERAGE THICKNESS

SD - STANDARD DEVIATION OF PRESENTED AREAS (SQ. IN.)

VAR - VARIANCE OF PRESENTED AREAS (IN. 4TH)

AVG+2 - AVERAGE PRESENTED AREA SQUARED (IN. 4TH)

ICDS - AREAS CALCULATED FROM ICOSAHEDRON GAUGE DATA

CALC - AREAS CALCULATED FROM APPROXIMATING RECTANGULAR PARALLELEPIPEDS

HEADINGS

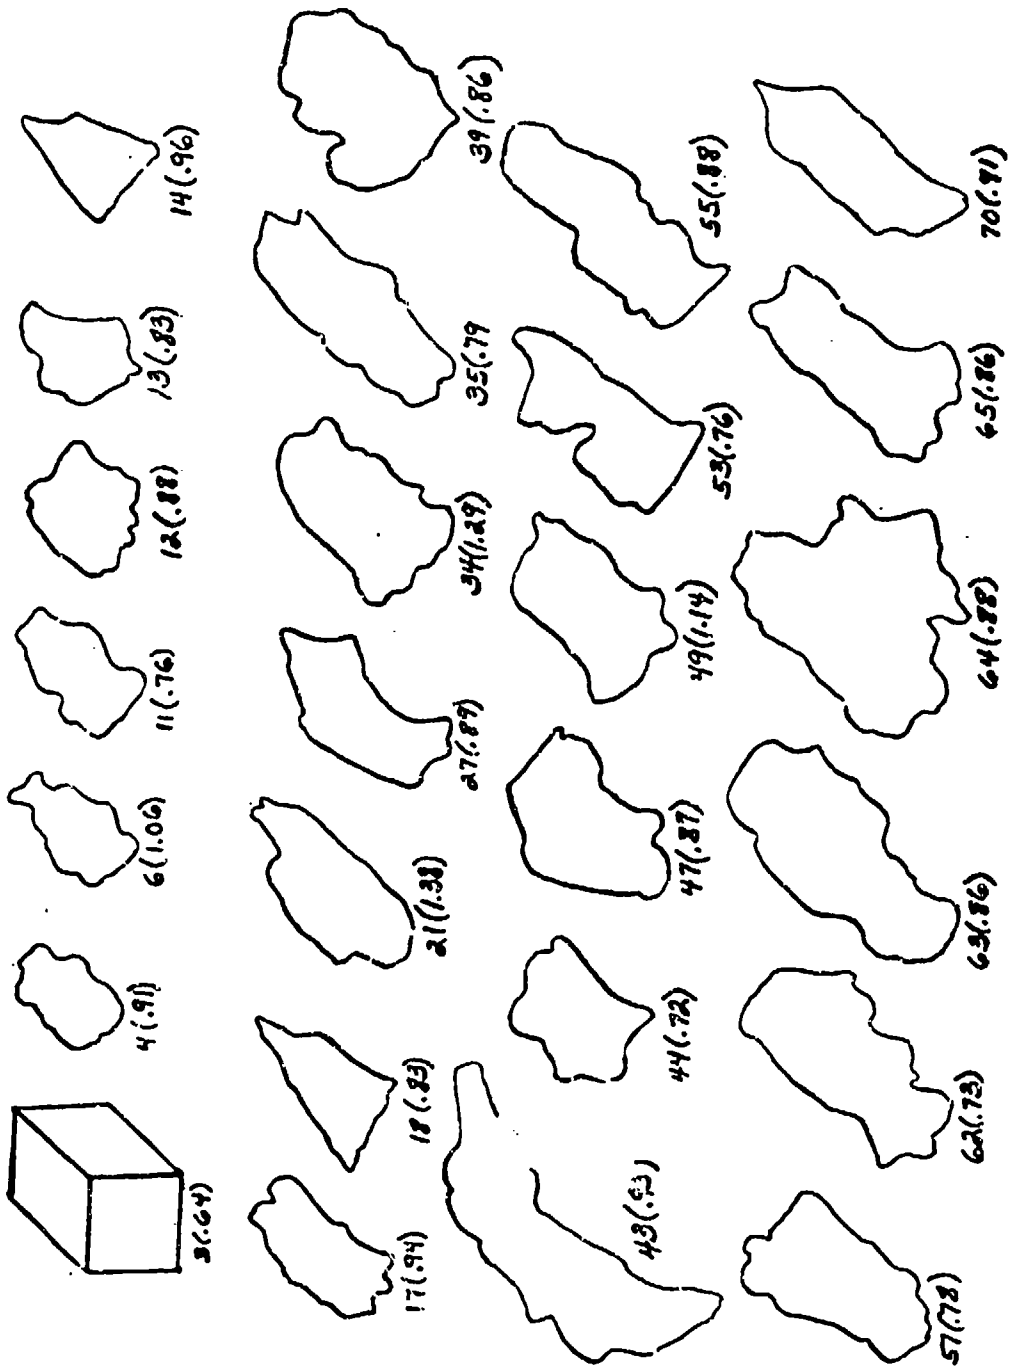

LWP - PERIMETER IN LW PLANE (IN.)  
 LTP - PERIMETER IN LT PLANE (IN.)  
 TWP - PERIMETER IN TW PLANE (IN.)  
 LMAX - MAXIMUM LENGTH (IN.)  
 WMAX - MAXIMUM WIDTH (IN.)
