REFLECTION OF FLEXURAL WAVES AT THE EDGE OF A PLATE

By

T. R. KANE

Office of Naval Research Project NR-064-388

Contract Nonr-266(09) Technical Report No. 6 CU-7-53-ONR-266(09)-CE February 1953

ABSTRACT

The reflection of straight-created flexural waves at the edge of a semi-infinite plate is studied in terms of a two-dimensional plate theory. It is found that, in general, a flexural wave propagated toward the edge at an arbitrary angle of incidence gives rise to three reflected waves: two flexural waves and a shear wave. A number of special cases, involving degenerate forms of these motions, are investigated in detail.

1. Introduction

In this paper Mindlin's $[1]^{1}$ equations of flexural motions of plates are used to study the reflection of a straight-orested wave at the edge of a semi-infinite plate. The equations accommodate three modes of motion: two types of flexural waves and a thickness-shear wave. It is found that, in general, all three of these motions are excited upon incidence of any one of them at a free edge. The shear motion, here encountered, is of particular interest; for this motion is absent in the classical theory of plates, whence the applicability of that theory is restricted to a range of frequencies considurably below that corresponding to the first mode of thickness-shear wibration. By the same token, the present theory does not include the higher modes of motion, which are to be found in three-dimensional elasticity theory; thus, the solution set forth below may be expected to furnish an adequate description for frequencies which do not materially exceed that of the first thicknessshear mode.

The character of the reflected waves is affected by both the angle of incidence and the ratio of plate thickness to wave-length of the incident wave. Appropriate values of these two parameters give rise to such special cases as waves whose amplitudes decrease exponentially with distance from the edge, vibrations, resonance, disappearance of some of the reflected waves, and, for grazing incidence, complete disappearance of the motion.

Following a resume of the plate equations in Section 2, straight-created waves are considered in Section 3. Incident and emergent waves are described in Section 4 and, in terms of these, a formal solution is reached in Section 5. In Sections 6 and 7 various cases of normal and oblique incidence are discussed in detail. Section 8 deals with grazing incidence.

^{1.} Numbers in brackets refer to the Bibliography at the end of the paper.

2. Plate Displacements, Equations of Motion and Stresses

For a plate of thickness h, oriented as in Fig. 1, plate displacements $\mathcal{H}_{x}(x, y, t)$, $\mathcal{H}_{y}(x, y, t)$ and w(x, y, t) are given by (see [1])

$$\begin{aligned} \mathcal{Y}_{X} &= \left[(r_{r} - 1) \frac{\partial w_{r}}{\partial x} + (r_{z} - 1) \frac{\partial w_{r}}{\partial x} + \frac{\partial H}{\partial y} \right] e^{ip t} \\ \mathcal{Y}_{Y} &= \left[(r_{r} - 1) \frac{\partial w_{r}}{\partial y} + (r_{z} - 1) \frac{\partial w_{r}}{\partial y} - \frac{\partial H}{\partial x} \right] e^{ip t} \\ \mathcal{W} &= (w_{r} + w_{r}) e^{ip t} \end{aligned}$$
(1)

The functions $W_i(x, y)$, $W_i(x, y)$ and H(x, y) are governed, respectively, by equations of motion

$$(\overline{P}^{*} + \overline{\delta_{i}}^{*})W_{i} = 0$$

$$(\overline{P}^{*} + \overline{\delta_{i}}^{*})W_{i} = 0$$

$$(\overline{P}^{*} + \omega^{*})H = 0$$
(2)

In the above,

Ŧ

$$(\tau, \tau_{\ell}) = (\delta_{\ell}^{2}, \delta_{\ell}^{2})(R\delta_{\ell}^{4} - 5^{-1})'' = (\delta_{\ell}^{2}, \delta_{\ell}^{-2})S\delta_{\ell}^{4}$$

$$2(\delta_{\ell}^{2}, \delta_{\ell}^{2}) = \delta_{\ell}^{4} \{S + R \pm [(S - R)^{2} + 4\delta_{\ell}^{-4}]^{\frac{1}{2}}\}$$

$$(3)$$

$$(I-\mu)\omega^{2} = 2(RJ_{0}^{*}-5^{-1})$$
⁽⁴⁾

$$\mathcal{D}_{\sigma}^{f} = \mathcal{D}_{\sigma}^{f} \qquad (5)$$

$$R = \frac{h^{2}}{\sqrt{2}}, \quad 5 = \frac{h}{\sqrt{4\pi h}}$$

$$O = \frac{Eh^{3}}{\sqrt{2}(1-\nu^{3})}, \quad (6)$$

p is the circular frequency associated with the wave motion. $\mathcal{L}, \mathcal{P}, \mathcal{P}$ are, respectively, Young's Modulus, Poisson's Ratio, and the mass density of the plate material.

Plate bending moments \mathcal{M}_x , \mathcal{M}_y , shears \mathcal{Q}_x , \mathcal{Q}_y and twisting moment \mathcal{M}_{yx} are given by

$$M_{x} = D\left(\frac{2\psi}{2x} + \frac{\omega}{2y}\right)$$

$$M_{y} = D\left(\frac{2\psi}{2y} + \frac{\omega}{2x}\right)$$

$$2M_{yx} = D(1-\omega)\left(\frac{2\psi}{2x} + \frac{2\psi}{2y}\right)$$

$$Q_{y} = \frac{\psi}{2}\omegah\left(\frac{\psi}{x} + \frac{2\psi}{2y}\right)$$

$$Q_{y} = \frac{\psi}{2}\omegah\left(\frac{\psi}{y} + \frac{2\psi}{2y}\right)$$

$$Q_{y} = \frac{\psi}{2}\omegah\left(\frac{\psi}{y} + \frac{2\psi}{2y}\right)$$

$$Q_{y} = \frac{\psi}{2}\omegah\left(\frac{\psi}{y} + \frac{2\psi}{2y}\right)$$

 μ is the modulus of rigidity of the plate material. The definition of κ^{L} is given in [1].

3. Straight-Created Waves

Taking any one of the functions w_i, w_i , or \mathcal{H} to be of the form

Aexpligx), g>0

and letting the remaining two vanish identically, we find that, in each case, two of the equations of motion are automatically satisfied while the remaining

-3-

one requires that

$$f^{2} = \begin{cases} \delta_{1}^{2} ; & \#_{1} \neq 0, & \#_{2} = H \circ 0 \\ \delta_{2}^{2} ; & \#_{2} \neq 0, & \#_{1} = H \circ 0 \\ \omega^{2} ; & H \neq 0, & \#_{1} = \#_{2} = 0 \end{cases}$$
(8)

Letting

this leads to [see Equations (3), (4), (5)] three possible types of relations ships between phase velocity C and wave number f:

$$\begin{aligned}
& \left\{ \begin{array}{c} \frac{\kappa}{\delta L} \left[\frac{\Gamma - (\Gamma^{*} - 4_{L} R5)^{N_{0}} R^{*}}{2\kappa} \right]^{N_{0}} ; & w_{i} \neq 0, & w_{i} = H = 0 \\
& \frac{\kappa}{\delta L} \left[\frac{\Gamma - (\Gamma^{*} - 4_{L} R5)^{N_{0}} R^{*}}{2\kappa} \right]^{N_{0}} ; & w_{i} = H = 0 \\
& \frac{\kappa}{\delta L} \left[\frac{\Gamma - (\Gamma^{*} - 4_{L} R5)^{N_{0}} R^{*}}{2\kappa} \right]^{N_{0}} ; & w_{i} = H = 0 \\
& \frac{\kappa}{\delta L} \left[\frac{2 + e^{3}(1 - 4r) 5}{R} \right]^{N_{0}} ; & H \neq 0, & w_{i} = W_{2} = 0 \end{aligned} \tag{9}$$

where

and C_3 is the velocity of shear waves in an infinite medium. A plot of C_{C_3} versus $h_{\mathcal{G}}$ (with y = 1/4) for each of these cases is shown in Fig. 3. It is seen that $C_{C_3} = 0$ as $h_{\mathcal{G}} = 0$ for a W_i wave, while $C_{C_3} = \infty$ as $h_{\mathcal{G}} = c$ for W_2 and H' waves. In the sequel we shall call W_i a "slow" flexural wave, W_2 a "fast" flexural wave and H' a shear wave. (The fact that the preceding discussion involves waves propagated in the X-direction, does not result in any loss of generality.)

-4-

Referring the semi-infinite plate to axes X, Y, Z as shown in Fig. 2 we consider a slow flexural wave² propagated towards the edge of the plate,

$$w_{t} = \dot{A}e^{i\varphi\psi}, \quad w_{z} = H = 0 \tag{10}$$

where

We postulate three emergent waves, propagated respectively towards $\mathcal{P}'_{,}\mathcal{P}''_{,}\mathcal{P}''$ as shown in Fig. 2. These are

a) a slow flexural wave:

$$w_{1}' = A' e' v_{2}' = H' = 0$$
 (11)

b) a fast flexural wave:

$$w_{2}^{*} = A^{"}_{2} e^{ig^{*}}, w^{*} = H^{2}_{-} 0$$
 (12)

o) a shear wave:

$$H'' = A'' e''' = w_{1}'' = w_{2}'' = 0$$
(13)

WI STS

and the α^{j} are the angles of emergence shown in Fig. 2.

In accordance with Equations (9), these waves are propagated with velocities C^{j} which depend on their respective wave numbers f^{j} .

^{2.} The case of a fast incident wave is similar in nature and will not be discussed in the present paper.

The displacements corresponding to these waves are obtained from Equation (1). Denoting the incident wave by $w_j \stackrel{\mathcal{W}}{\downarrow_x}$ and $\stackrel{\mathcal{W}}{\downarrow_y}$, and calling the displacement components of the emergent waves $w^j, \stackrel{\mathcal{W}}{\downarrow_x} \stackrel{\mathcal{W}}{\downarrow_y} \stackrel{\mathcal{W}}{\downarrow$

$$\chi^{*} = W + \sum_{j} W^{j}$$

$$\mathcal{Y}_{x}^{*} = \mathcal{Y}_{x} + \sum_{j} \mathcal{Y}_{x}^{j}$$

$$\mathcal{Y}_{y}^{*} = \mathcal{Y}_{y} + \sum_{j} \mathcal{Y}_{y}^{j}$$
(14)

is a possible state of motion for an infinite plate. For the semi-infinite plate under consideration, three boundary conditions must be satisfied on the edge X = O.

5. Boundary Conditions

Plate stresses $\mathcal{M}_{\chi}^{*}, \mathcal{M}_{\chi}^{*}$, etc. corresponding to the motion defined by Equations (14) may be computed from Equations (7). To obtain a traction-free edge, we must have, on $\chi=0$,

$$M_{x}^{*} = M_{yx}^{*} = Q_{y}^{*} = 0.$$
 (15)

In order that these equations be satisfied for all values of the time $\not\subset$ and all values of the space variable φ , it is necessary that the circular frequencies \wp and \wp' associated with the various waves be identical, i.e.,

$$f^{c} = f^{j} c^{j}, \qquad (16)$$

and that the angles \propto and \propto^{j} satisfy

$$f \sin \alpha + f^{j} \sin \alpha^{j}.$$
 (17)

Now, the relation between C and g is of the same form as that between C'and g', both being slow flexural waves. Thus it follows from Equations (16) and (17) that the angle of emergence α' of the slow flexural wave is equal to the angle of incidence α' of the incident wave, and that the wave numbers and phase velocities of these two waves are identical. Equations (16) and (17) show, furthermore, that the condition of vanishing traction at the edge of the plate, [Eq. (15)], loads to a determination of the phase velocity, wave number and angle of emergence of each of the postulated emergent waves when the argle of incidence and wave number (or phase velocity) of the incident wave are specified. ्रित्र संभ कामरों का को बात के को संक्षेत्र की समें न का का का महिला न कर के महान के प्रतिक्रिय **की विश्व के क**ि

The boundary conditions (15) also impose restrictions on the amplitude ratios A^{i}/A . From Equations (10)-(13), (14) and (7) we get, upon substitution into Equations (15), a system of three non-homogeneous linear algebraic equations governing these amplitude ratios,

$$\sum_{n=1}^{\infty} A'_{n} = -\frac{2}{\sqrt{2}} P'_{n} \cos[(2n-1)\pi], j-j^{n}, j+n-1, 2, 3 \qquad (18)$$

where

$$\begin{aligned} \varphi_{i}^{j} &= \mathcal{M}^{j} \varphi_{i}^{j}, \quad j = j^{*} \\ \varphi_{i}^{\prime \prime \prime \prime \prime \prime} &= (1 - \nu) \varphi_{i}^{*} sin \alpha^{2} cos \alpha^{2\prime} \\ \varphi_{2}^{\prime \prime \prime} &= \mathcal{M}^{j} sin 2 \alpha^{\prime}, \quad j = j^{\prime \prime \prime} \\ \varphi_{2}^{\prime \prime \prime} &= - \varphi_{i}^{\prime \prime \prime \prime} cos 2 \alpha^{\prime \prime \prime} \\ \varphi_{3}^{\prime \prime \prime} &= - \xi_{0}^{\prime \prime \prime \prime} cos \alpha^{\prime \prime}, \quad j = j^{\prime \prime \prime} \end{aligned}$$

$$(19)$$

$$\begin{aligned} \varphi_{3}^{\prime \prime \prime} &= \int_{0}^{2} (\varphi_{i})^{-j} cos \alpha^{\prime \prime}, \quad j = j^{\prime \prime \prime} \\ \varphi_{3}^{\prime \prime \prime} &= \int_{0}^{2} sin \alpha \end{aligned}$$

with

$$M^{j} = 55^{a} - (1)^{2}$$

$$\Theta^{j} = \cos^{3}\alpha^{j} + \sin^{2}\alpha^{j}.$$

The analog, in the present theory, to F. Neumann's uniqueness theorem [2] guarantees that the above constitutes the unique solution of the problem. We may say then that a slow incident flexural wave produces, in general, three reflected waves: a slow flexural, a fast flexural, and a shear wave.

6. Normal Incidence

We now proceed to study the character of the reflected waves in terms of the angle of incidence \propto and the wave number ρ of the incident wave. We begin by examining the case of normal incidence, i.e., $\alpha = 0$.

The wave numbers \mathcal{J}'' and \mathcal{J}'' of the fast reflected wave and of the shear wave are given by [see Eqs. (8), (4), (5)]

$$2(y^{*})^{2} = \tilde{\omega}^{4} \left[S + R - \left[(S - R)^{2} + 4 \tilde{\omega}^{*} \right]^{2} \right]$$
(20)

$$(y'')^{2} = 2(1-\nu)^{-1}(R\delta_{0}^{2}-5^{-1})$$
(21)

Both f'' and f''' vanish when $R55_0^+ 1$, i.e., when f'R5 = R+5. For $f^*R5 < R+5$, f'' and f''' are imaginary while for $f^*R5 > R+5$ both are real. The physical significance of $f^*R5 = /$ will be discussed when the motion corresponding to that value of the wave number of the incident wave has been determined. We first consider

From Eq. (17) we have, for $\propto = O$

at=0, j=', *, ".

The amplitude ratios are found from Eqs. (18):

$$\begin{array}{c}
A' - A + \frac{i}{A} \\
A' - A + \frac{i}{A} \\
A' - A + \frac{i}{A} \\
A + \frac{i$$

where

$$\frac{G_{i}}{A} = \frac{(3^{n})^{2} (S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2}}{(\tilde{f}^{n})^{2} (S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{2} (S_{i} \int_{0}^{a} - \tilde{g}^{a})^{2}} \\
\frac{b_{i}}{A} = -\frac{2\tilde{g}^{a} ((S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{a} (S_{i} \int_{0}^{a} - \tilde{g}^{a})}{(\tilde{g}^{a})^{2} (S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{2} (S_{i} \int_{0}^{a} - \tilde{g}^{a})^{2}} \\
\frac{b_{i}}{A} = -\frac{2\tilde{g}^{a} ((S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{a} (S_{i} \int_{0}^{a} - \tilde{g}^{a})}{(\tilde{g}^{a})^{2} (S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{2} (S_{i} \int_{0}^{a} - \tilde{g}^{a})^{2}} \\
\frac{b_{i}}{A} = -\frac{2\tilde{g}^{a} ((S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{a} (S_{i} \int_{0}^{a} - \tilde{g}^{a})^{2}}{(\tilde{g}^{a} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{2} (S_{i} \int_{0}^{a} - \tilde{g}^{a})^{2}} \\
\frac{b_{i}}{A} = -\frac{2\tilde{g}^{a} ((S_{i} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{a} (S_{i} \int_{0}^{a} - \tilde{g}^{a^{2}})^{2}}{(\tilde{g}^{a} \int_{0}^{a} + \tilde{g}^{a^{2}})^{2} + \tilde{g}^{2} (S_{i} \int_{0}^{a} - \tilde{g}^{a^{2}})^{2}} \end{aligned}$$

and

$$\bar{g}^{\prime}=-ig^{\prime},$$

so that ξ'' is real.

The incident wave is given by [see Eqs. (1) and (10)]

$$W = A \cos_{f} (x + ct)$$

$$W = -A M'_{f} - sin_{f} (x + ct)$$

$$W = 0$$

$$(23)$$

$$w' = A \cos \varphi (x - ct + l,)$$

$$\Psi_{x}' = -A M_{\varphi}' = ' \sin \varphi (x - ct + l,)$$

$$\Psi_{y}' = 0$$

and the fast reflected wave [Eq. (12)] is given by

$$W'' = (a_{2}^{2} + b_{2}^{2})^{42} e^{-b^{2}x} \cos(pct - e_{1})$$

$$Y_{x}^{*} = (\bar{e}^{-})^{-1} (5\bar{e}^{-} - \bar{e}^{+2}) W''$$

$$Y_{y}^{*} = 0$$

In the above,

$$l_{\kappa} = \arctan \frac{b_{\kappa}}{a_{r}}, \kappa - i_{s} c$$

We see that the slow reflected wave has the same amplitude, wave-length and velocity as the incident wave, but is out of phase with it. The fast reflected "wave" is, in fact, a <u>vibration</u>, the amplitude of which decreases exponentially as the distance from the edge of the plate increases. As $\mathcal{A}'''=0$ by Eq. (22), no other waves are reflected.

Now consider

Equations (22) are then replaced by

$$\frac{A'}{A} = \frac{\varphi^{*}(55_{0}^{*} - \varphi^{*}) + \varphi(55_{0}^{*} - \varphi^{*})}{\varphi^{''}(55_{0}^{*} - \varphi^{*}) - \varphi(55_{0}^{*} - \varphi^{*})}$$

$$\frac{A''}{A} = \frac{2(55_{0}^{*} - \varphi^{*}) - \varphi^{*}(55_{0}^{*} - \varphi^{*})}{\varphi(55_{0}^{*} - \varphi^{*}) - \varphi^{*}(55_{0}^{*} - \varphi^{*})}$$

$$\frac{A'''}{A} = 0$$

The incident wave remains unchanged [Equations (23)], the slow reflected wave becomes

$$w' = A' \cos_{\ell} (x - ct)$$

$$Y'_{x} = -A' M'_{0} c' sin_{\ell} (x - ct)$$
(26)

$$Y'_{y} = 0,$$

ي يوني <mark>كالأيد الاخ</mark>لامي 19 في 14 م م

the fast reflected wave is given by -

$$w' = A'' cos e^{*} (x - e^{*}t)$$

$$Y'_{x} = -A'' M'' (e^{*})^{-} sin_{e}^{*} (x - e^{*}t)$$

$$Y'_{y} = 0,$$
(27)

and the reflected shear wave again vanishes. (The amplitude ratios A'/A and A''/A for this case are plotted versus $h_{a'}$ in Fig. 4.)

The incident wave is seen to give rise to two reflected flexural waves; we may examine the manner in which the energy per unit length of wave-front, per cycle, of the incident wave is distributed to the two reflected waves. Using the expressions for energy given in Raference [4], we find

$$\frac{E'}{E} = \left(\frac{A'}{A}\right)^{2}$$

$$\frac{E}{E} = \left(\frac{A'}{A}\right)^{2} \left(\frac{\mu}{\delta^{2}}\right) \frac{\overline{\delta^{2}}}{\overline{\delta^{2}} + M^{2}}$$

Here \mathcal{E} , \mathcal{E}' and \mathcal{E}' are, respectively, the energy per cycle, per unit length of wave front of the incident wave, for the incident, slow reflected and fast reflected waves. The ratios $\mathcal{E}'\!/\!\mathcal{E}$ and $\mathcal{E}''\!/\!\mathcal{E}$ are plotted versus $h_{\mathcal{F}}$ in Fig. 5.

~11-

The motion corresponding to

may be found by proceeding to the limit, as $\mathcal{F}^*\mathcal{R} \longrightarrow \mathcal{R} \not \rightarrow \mathcal{R} \rightarrow \mathcal{F}$, in either of the preceding cases. By either method it may be verified that an incident wave

$$W = A c_{35f}(x+ct)$$

$$Y_{y} = A \sqrt{\frac{R}{15(R+5)}} sin_{f}(x+ct) \qquad (28)$$

$$Y_{y} = 0$$

now gives rise to a slow reflected wave,

$$w' = -A\cos \varphi (x-ct)$$

$$W' = -A|\sqrt{\frac{R}{S(R+S)}}sin\varphi (x-ct)$$
(29)

$$U' = 0$$

and to a thickness-shear vibration,

$$W'' = 0$$

$$\frac{W''}{2} = 2A \left| \frac{5}{R(R+5)} \sin yet \right|$$
(30)
$$\frac{W''}{4} = 0$$

The circular frequency p for this vibration is [see Eqs. (3), (5), (6), (8), (9)]

Now, the oircular frequency, $\overline{\rho}$, of the first antisymmetric mode of thicknessshear vibration of an infinite plate, according to the three-dimensional theory of elasticity, is

$$\overline{p} = \frac{TC_s}{h}$$

Thus it seems appropriate to let

K = T

so that the thickness-shear vibration in the present case will occur at the frequency predicted by exact theory for an infinite plate of the same thickness.

It is interesting to notice that the motion here being considered, is one of the possible modes of motion of an infinite strip of thickness / and width b (see Reference [3]), provided

Hence, for $\sqrt{R5 \cdot R + 5}$, i.e., for $p = \overline{p}$, the semi-infinite plate may be regarded as consisting of an infinite number of independently vibrating strips, each with its infinite dimension parallel to the edge of the plate.

To conclude the discussion of normal incidence, we consider two limiting cases:

When the wave-length of the incident wave is large in comparison with the thickness of the plate, we find, by proceeding to the limit in Equations (22)-(25), as $h_f \rightarrow 0$

$$w = Acosy(x+ct)$$

$$Y_x = Agsing(x+ct)$$

$$Y_y = 0$$

$$w' = -Asing (x-ct)$$

$$y'_{x} = -Ag \cos g (x-ct)$$

$$y'_{y} = 0$$

$$w'' = Ae^{-\delta x} (cospet + singet)$$

$$y'_{x} = -Ag e^{-\delta x} (cospet + singet)$$

$$y'_{y} = 0$$

$$w'' = 0$$

These expressions show that the incident wave is reflected without change in amplitude or phase velocity, and that a vibration, confined primarily to a region near the edge of the plate, takes place. The classical theory of plates (whose range of applicability is restricted to the limiting case under consideration) predicts the same results.

For wave-lengths which are very small in comparison with the plate thickness³, we let $h_{\mathcal{F}}$ approach infinity in Equations (26), (27) with the result

> $w = A \cos_{f}(x + ct), \quad \forall_{x} = \psi_{y} = 0$ $w' = A \cos_{f}(x - ct), \quad \forall_{x}' = \psi_{y}' = 0$ $w'' = \psi_{x}'' = \psi_{y}'' = 0$ $w''' = \psi_{x}''' = \psi_{y}'' = 0$

^{3.} The theory is not expected to be good for very short waves. This limiting case is included for the sake of completeness.

The total motion is

which is a standing wave.

7. Oblique Incidence

We have seen that fundamentally different states of motion obtain according as the circular frequency of the incident wave is less than, equal to, or greater than the circular frequency of thickness-shear vibration of an infinite plate. Hence, for $0 < \alpha < \frac{\pi}{2}$ we shall again examine separately the cases $p < \bar{p}$, $p > \bar{p}$ and $p = \bar{p}$.

p<b

Is $\beta < \beta$ is equivalent to $RSS_{\delta} < /$, we see from Equations (20) and (21) that ρ'' and $\rho'''' are imaginary.$

Setting

we get, from Equation (17),

$$sinx^{j} = -\frac{i}{2} e^{sinx}, j = \int_{a}^{a} e^{sinx}$$

whence

$$\cos \alpha^{j} = \left[1 + \left(\frac{d}{d^{j}} \right)^{2} \sin^{2} \frac{d^{2}}{d^{2}} - m^{j}, \quad say.$$

(For all values of α and β we have, as noted earlier, $\psi'_{\alpha}, c' \in \alpha' \cdot \alpha$.)

Substituting into the general expressions for the various reflected waves [Equations (11), (12), (13)], we get from Equations (1),

w' A exp[ig(xconx+5)] Y' = W'Mg'cask "y'= W'M'z= 'ising

W" = A" exp (if S-j" m"x) " " W M'm" 44 - - W M "(j ") + sind

W= 0 4 = A"i y sin x exp (if \$ - J"m"x) 4 = A" J"mm" exp (if \$ - J"m"x)

where

These expressions are valid for all \propto with the possible exception of $\propto = 7/2$, i.e., "grazing" incidence. For that case, the solution of Equations (18) is

(31)

and we get, in place of Equations (31),

$$w' = -w_{y} y_{x}' = -y_{x} y_{y}' = -y_{y}' y_{y}' = -$$

so that the entire motion is then [see Eq. (14)]

$$W^{*} = Y_{x}^{*} = Y_{y}^{*} = 0.$$
 (32)

This complete disappearance of the motion is analogous to the case of grazing incidence in the reflection of plane waves from the plane boundary of a semi-infinite solid. We shall return to this question later on.

The waves described by Equations (31) are

1 - a slow flexural wave, reflected at an angle equal to the angle of insidence of the insident wave.

a fast flexural wave of amplitude decreasing exponentially with
 departure from the edge, and propagated in a direction papallel to the edge,
 a shear wave of exponentially decreasing amplitude, propagated slong the edge. (See Fig. 6.)

Turning now to the case

we note that, from Equations (20) and (21)

$$\frac{dt''}{dt} < 1, \frac{dt''}{dt} < 1 \text{ and } \frac{dt''}{dt} < \frac{dt''}{dt} \quad \text{for all } \varphi.$$

(Fig. 8 illustrates these facts for -/4.)

Equation (17) permits us to construct a table which shows the relationship between \propto and \propto', \propto'' , \propto''' in terms of trigonometric functions of these angles.

With the help of this table and Equations (10)-(13) we can now describe the motion associated with various angles of incidence.

For $0 \leq sinx < e^{y/4}$, the reflected waves are

1 - a slow flexural wave,

a fast flexural wave,

(3) - a shear wave

-

These emerge at angles $\propto', \, \alpha'', \, \alpha'''$ with

x= <'< x'''< x "< T/2

> $\alpha' = 15^{\circ}$ $\alpha'' = \arcsin \frac{.259}{.302} = 59.1^{\circ}$ $\alpha''' = \arcsin \frac{.259}{.593} = 25.9^{\circ}$

For $Since \frac{d}{dt}$, the amplitude ratios [see Eqs. (18)] are

$$\frac{A'}{A} = l, \quad \frac{A''}{A} = \frac{2(5\delta_0^{-} + 2)}{\nu(5\delta_0^{-} + 2)} \left[\left(\frac{\partial \mu}{\partial \mu} \right)^2 (1 - \nu - 1) \right], \quad \frac{A'''}{A} = 0.$$

Thus we have only two reflected waves, (see Fig. 9),

 A slow flexural wave whose angle of emergence is equal to the angle of incidence of the incident wave,

(2) - a fast flexural wave propagated along the free edge.

with $h_{f'}$ = 5, as in the numerical example above, the critical angle, α'_{f} , for which the shear wave vanishes, is

 $\alpha_a = \arcsin (.302) = 17.6^{\circ}$

Letting α increase further, until $\partial \partial \partial \alpha < \partial \alpha = \partial \partial \partial \partial \alpha$, we find that the fast flexural wave [Equations (12)] changes in character since $\cos \alpha''$ is now imaginary. The shear wave reappears and we have (Fig. 10)

1) - a slow flexural wave,

2) - an exponentially decaying tast flexural wave, propagated parallel to the edge.

-3 - a shear wave emerging at an angle, α'' , with $\alpha' < \pi/2$.

Another oritical value of x is reached when $sin x \in \mathcal{T}'_{\mathcal{T}}$. We then find (Fig. 11)

a slow flexural wave,

2. an exponentially decaying fast flexural wave,

3) - 🐁 sheer wave.

Both (and (3) are now propagated along the edge. With $h_{j'} = 5$, the critical value for α is 36.4.

Finally, for $J''/J < \sin \alpha < /$, the shear wave also acquires an exponentially decaying amplitude, giving us (Fig. 12)

1 - a slow flexural wave,

(2) - an exponentially decaying fast flexural wave,

(3) - an exponentially decaying shear wave.

Grazing incidence, i.e., $\alpha = 90^{\circ}$, leads to vanishing motion, as it did for $p < \overline{p}$.

To complete the discussion of oblique incidence, we consider the case

<u>p=</u><u></u>

As the circular frequency of the incident wave approaches the thicknessshear frequency, the amplitudes of the fast reflected wave and of the reflected shear wave become infinite. The resonance encountered here is due to the fact that reflection at the edge of the plate is equivalent to "forcing" the plate at a frequency equal to a "natural" frequency. For, it may easily be verified that the vibration

Work= 0 Y = Beist

is a motion which satisfies the equations of motion (2) and leaves the edge $\lambda = 0$ free-of traction.

8. Grasing Incidence

We have seen [Eq. (32)] that the wave motion in a semi-infinite plate disappears as the angle of incidence approaches 90°. A similar situation obtains in the case of waves reflected from the plane boundary of a semi-infinite solid. By application of a suitable limiting process, wave motions for the latter case have recently been found by Goodier and Bishop [4]. A similar limiting process for the present case will now be considered.

Letting

and neglecting higher powers of ϵ , we have, from Equations (17),

 $Sin M^{J_a} \not\subset (I - \not\in I), j \in J^{*}.$

-20-

Substituting into Equations (12), the amplitude ratios are found to be of the form

$$\frac{A'}{A} = -(1+a'\epsilon), \quad \frac{A'}{A} = a'\epsilon, \quad \frac{A''}{A} = a''\epsilon$$
(33)

Expanding the exponentials which appear in the expressions for displacements, we get from Equations (10)-(13) and Equation (1),

(34)

.vhere

E = y-et fi = [g-(gi)*]^{1/2}, j=","".

These expansions are valid only when higher powers of $y \in X$ can be neglected, that is, for a range of distances from the edge which is small in comparison with the unverlength of the incident wave.

From Equations (14), (32) and (34), the total motion is characterized by the expressions

$$W = A \in [-a' - Zigx + a'' = \int up(ig \in G)$$
(35)

$$H^{*'} = A \in a^{*} \exp(igy - xf^{*'}). \tag{36}$$

If we now permit A to become infinite as ϵ approaches zero, and let the approach to infinity be such that the product $A\epsilon$ remains finite, we see that the first term of Equation (35) represents an incident flexural wave while the second term corresponds to the " P_{μ} " wave found by Goodier and Bishop. The third term and Equation (36) indicate, respectively, a flexural and a shear wave, each propagated along the edge of the plate, and each having an exponentially increasing or decreasing amplitude, according as p is less than or greater than \bar{p} ; for $p = \bar{p}$ we again have resonance.

Asknowledgeent

The author vishes to thank Professor R. D. Mindlin of Columbia University both for suggesting this problem, and for his helpful advice in Lis solution.
