**Atmospheric Attenuation Model, 1964, in the Ultraviolet ,
Visible, and Infrared Regions for Altitudes to 50 km**

L. ELTERMAN

Abstract

A model of a clear standard atmosphere, for determining attenuation in the ultraviolet, the visible, and the infrared windows, is derived. The derivation is based on a Rayleigh atmosphere combined with aerosol and ozone components. The format of the model is a series of tabulations for 22 wavelengths with Rayleigh, aerosol, and ozone components arrayed at kilometer intervals to an altitude of 50 kilometers. Exploratory calculations pertaining to horizontal, vertical, and slant-path transmission from sea level, transmission between two altitudes and transmission to space are readily made from the tabulations. Because of its more extensive coverage and improved computational programming, this report, including the tabulations, fully replaces the earlier publication, "A Model of a Clear Standard Atmosphere for Attenuation in the Visible Region and Infrared Windows," by this author.

Atmospheric Attenuation Model, 1964, in the Ultraviolet, Visible, and Infrared Regions for Altitudes to 50 km

1. INTRODUCTION

In this paper, a "standard atmosphere" is distinguished from a "clear standard atmosphere"¹ in that the latter is characterized by aerosol and ozone attenuating components in addition to the molecular or Rayleigh component. A model of a clear standard atmosphere for determining absorption and attenuation in the ultraviolet, the visible, and the infrared windows is useful for interpreting the optical properties of the atmosphere and can function like the U.S. Standard Atmosphere, as an information source for carrying out various exploratory calculations. The derived tabulations at the end of this report are based on the following:

- a. The Rayleigh attenuation components are determined by utilizing Rayleigh scattering cross sections with molecular number densities from the U.S. Standard Atmosphere.
- b. The aerosol attenuation components are established from available transmission measurements in conjunction with a suitable vertical aerosol density distribution.
- c. The ozone absorption components result from Vigroux's coefficients applied to a generalized vertical ozone distribution.

This approach describes the atmosphere vertically in terms of Rayleigh and aerosol attenuation coefficients, atmospheric ozone absorption coefficients as well optical thickness values.

(Received for publication 27 July 1964)

The model concept is readily workable for a molecular atmosphere and has been computed by Deirmendjian.² Sekera computed a family of curves showing the variation of the optical thickness of the molecular atmosphere with height and with wavelength.³ Extending this concept to include an aerosol component and an ozone component is more difficult primarily because it must be compatible with considerable variation of atmospheric properties. The model concept for both sea level and with altitude has been examined previously by Deirmendjian for several atmospheres containing different computed aerosol size distributions⁴ and by Volz and Goody in conjunction with their illumination profiles of twilight intensity.⁵

Fundamental to the establishment of this model is a definition of "clear standard atmosphere" which is adequately representative and which lends itself to quantitative treatment. Toward this end, reference is made to the long path transmission measurements of Yates and Taylor,⁶ Dunkelmann and Baum,^{7,8} and Curcio, Knestrick, Cosden, and Durbin.^{9,10,11} In these instances experimental data were obtained showing relationships between wavelength and attenuation coefficients for various meteorological ranges at sea level.

The International Visibility Code¹² designates a clear day as one with a daylight visual range having an upper limit of 20 km and a corresponding attenuation coefficient of 0.2 km^{-1} at 0.52 microns. Accordingly, it is reasonable to define a "clear standard atmosphere" as the latest published standard atmosphere augmented by an aerosol component yielding a resultant meteorological range of about 25 km at sea level. The aerosol size distribution is considered to be unchanged with altitude.¹³ Ordinarily, the meteorological range is related to visual background contrast at 0.55 microns. In this definition of a clear standard atmosphere the meteorological range is also associated with the other wavelengths.

Although the development of this model requires the addition of a haze component to a Rayleigh atmosphere, the designation "clear standard atmosphere" is preferred to "hazy standard atmosphere" for the reason that the haze component that characterizes a meteorological range of 25 kilometers would empirically be associated with clear conditions. Thus, use of "hazy" in identifying this model can result in misinterpretation.

2. RAYLEIGH PARAMETERS

Because they are widely used, three Rayleigh parameters are derived for each wavelength: attenuation coefficients as a function of altitude, optical thickness from sea level to a desired altitude, and optical thickness from a desired altitude to space. The Rayleigh cross section is expressed by

$$\sigma_r = \frac{8\pi^3(n_s^2 - 1)^2}{3\lambda^4 N_s^2} \cdot \frac{6 + 3\delta}{6 - 7\delta} \quad (1)$$

where

- σ_r is the Rayleigh scattering cross section (cm^2),
- λ is the wavelength (cm),
- n_s is the index of refraction of air at 15°C and 1013 mb pressure,
- N_s is the molecular number density at sea level for a standard atmosphere (cm^{-3}).

and

δ is the depolarization factor.

The term $(6 + 3\delta)/(6 - 7\delta)$ accounts for the degree of depolarization attributable to the anisotropy of the medium. The depolarization factor has been determined by calculation and by laboratory measurement. The latest work of Gucker and Basu¹⁴ yields $\delta = .035$. The values of σ_r as expressed by Eq.(1) were calculated by Penndorf¹⁵ for wavelengths from 0.20 to 20.0 microns. For wavelengths concerned with this report, the values of σ_r are listed in Table 1. The use of Eq.(1) excludes several customary simplifications thus eliminating up to 10 percent error.

2.1 Rayleigh Attenuation Coefficients

The Rayleigh attenuation coefficient at each wavelength is expressed by

$$\beta_r(h) = \sigma_r \cdot N_r(h) \cdot 10^5 \quad (2)$$

where

- β_r is the Rayleigh attenuation coefficient (km^{-1}),
- σ_r is the Rayleigh scattering cross section (cm^2),

and

N_r is the molecular number density (cm^{-3}).

The values of $N_r(h)$ needed for Eq.(2) were obtained from the U.S. Standard Atmosphere, 1962.¹⁶ This expression is used to compute an array of Rayleigh attenuation coefficients as a function of altitude for each wavelength.

2.2 Rayleigh Optical Thickness from Sea Level to Altitude h

With the Rayleigh attenuation coefficients determined, then for each wavelength

$$\tau_r(h) = \sum_0^h \bar{\beta}_r(h) \cdot \Delta h \quad (3)$$

TABLE 1. Rayleigh cross sections, $\sigma_r(\lambda)$ and

2.17	1.800	0
3.50	2.681×10^{-30}	0
4.00	1.571	0

where

$\bar{\beta}_r$ is the mean Rayleigh attenuation coefficient (km⁻¹) for each altitude increment, and

Δh is the altitude increment, chosen as one km for these calculations.

2.3 Rayleigh Optical Thickness from Altitude h to Space

The relationship, for each wavelength considered, is

$$\tau'_r(h) = \tau_r(\infty) - \tau_r(h) \quad (4)$$

where $\tau_r(\infty)$ is the Rayleigh optical thickness from sea level to infinity. The term $\tau_r(\infty)$ was obtained by using Eq.(3) with the limits set between 0 and 80 km.

Above 80 km, $\int_{80}^{\infty} \bar{\beta}_r dh$ can be neglected.

3. ABSORPTION BY ATMOSPHERIC OZONE

In the studies of ultraviolet, visible, and infrared transmission of the atmosphere, the concept of a representative ozone distribution as a function of altitude, based on many observations, is necessary for carrying out exploratory calculations. This need was met somewhat formally with the publication of the 1957 edition of the Handbook of Geophysics¹⁷ which contained eight ozone profiles. These were in considerable use at least by meteorologists, and the material was reproduced unchanged in a later edition. In 1961 an ozone distribution was proposed by Altshuler¹⁸ which was characterized by 0.229 cm N.T.P. total ozone and a maximum concentration at 23 km. This has been designated as a "standard" distribution by Hubbard,¹⁹ by Green,²⁰ and by others either directly, or indirectly through the references mentioned.

Ozone data acquired since Altshuler's publication show that a representative ozone profile differs substantially from the designated "standard". The Handbook of Geophysics and Space Environment²¹ scheduled for publication in 1964 will provide mean values of ozone distribution based on a network of 12 ozonesonde stations in North America. It is emphasized that an exploratory calculation will be better if a profile that is related to latitude and season is used. If only one profile is to be used it should be one representing 0.35 cm total ozone since the work of London, Ooyama, and Prabhakara²² shows that for mid-latitudes the 0.35 cm value is the annual mean. The profile shown in Figure 1 is based on the material to be published in the Handbook. Furthermore, the profile has been extended upward by utilizing values at 40 km and 50 km derived from chemical equilibrium theory. Values of ozone concentration between these altitudes were derived by interpolation (using semilog paper). This profile provides the ozone concentrations, $D_3(h)$, listed in Table 2.

The parameter for determining absorption of the ultraviolet as a function of altitude is the atmospheric ozone absorption coefficient expressed by

$$\beta_3(h) = A_v \cdot D_3(h) \quad (5)$$

where

β_3 is the atmospheric ozone absorption coefficient (km^{-1}),
 A_v is the Vigroux ozone absorption coefficient (cm^{-1}),

and

$D_3(h)$ is the ozone equivalent thickness or concentration (cm/km).

Thus the Vigroux coefficients²³ (Table 1) in conjunction with the 1964 profile permit the computation of an array of atmospheric ozone absorption coefficients to 50 km for each of the desired wavelengths.

Figure 1. Representative Ozone Concentration Profiles

4. AEROSOL ATTENUATION

As with Rayleigh attenuation and ozone absorption, the fundamental parameter to be used is the aerosol attenuation coefficient. Junge's findings¹³ that the aerosol size distribution tends to be unchanged with altitude permits the relationship

$$\beta_p(h) = \beta_p(0) \cdot \frac{N_p(h)}{N_p(0)} \quad (6)$$

$\beta_p(0)$ is the aerosol attenuation coefficient at sea level for a meteorological range of 25 km (km^{-1})

$N_p(h)$ is the aerosol number density as a function of altitude (cm^{-3})

$N_p(0)$ is the aerosol number density at sea level for a meteorological range of 25 km (cm^{-3})

To determine values for $\beta_p(h)$, three kinds of information are necessary as designated by the right hand side of Eq.(6). Each of these now will be considered.

4.1 Aerosol Attenuation Coefficients at Sea Level

Aerosol attenuation is determined by aerosol density which in turn determines meteorological range. The relationship between the aerosol attenuation coefficient and the meteorological range, although established in the visible region, is applicable to the other wavelengths when the measurements are performed over a wider spectral region.

In the ultraviolet, Dunkelman and Baum^{7,8} carried out transmission measurements at sea level that yielded extinction coefficients between wavelengths 0.297 and 0.578 microns for various meteorological ranges. The term extinction is used since the coefficients represent the total attenuation at sea level as expressed by

$$\beta_{\text{ext}}(0) = \beta_r(0) + \beta_3(0) + \beta_p(0) \quad (7)$$

where

- $\beta_{\text{ext}}(0)$ is the extinction coefficient (km^{-1}),
- $\beta_r(0)$ is the Rayleigh attenuation coefficient (km^{-1}),
- $\beta_3(0)$ is the atmospheric ozone absorption coefficient (km^{-1}),

and

- $\beta_p(0)$ is the aerosol attenuation coefficient (km^{-1}).

Of particular interest are the results of Dunkelman and Baum for the period February to April 1950 which include measurements at the same location and for approximately the same visual range as Curcio, *et al.*⁹ The ultraviolet results are presented in curve (1) of Figure 2. The presence of strong atmospheric ozone absorption is indicated by the sharp rise of the extinction coefficients at wavelengths shorter than 0.32 microns. In order to determine the aerosol component, β_p of curve (1), the other components as expressed by Eq.(7) must be known. The Rayleigh component was determined by calculating values of β_r for sea level using Eq.(2) with $h = 0$. These values were then subtracted from curve (1) yielding curve (2). The β_3 component is expressed by Eq.(5) with $h = 0$. The surface ozone concentration $D_3(0)$ intrinsic to curve (2) can be determined by trial. For example, assuming a sea-level ozone concentration of 2.5×10^{-3} cm/km yields a series of atmospheric ozone coefficients, which when subtracted from curve (2), yield curve (4). Obviously, the O_3 concentration chosen is too high since the curve is strongly depressed. Further trials show a surface O_3 concentration of 1.8×10^{-3} cm/km approximates the proper value since it yields curve (3) where the trend of the curve is maintained at the shorter wavelengths. Curve (3) now can be extrapolated from 0.297 to 0.270 microns as shown. Accordingly, these values represent the aerosol attenuation coefficients at sea level $\beta_p(0)$ for a meteorological range

Figure 2. Derivation of Aerosol Attenuation Coefficients in the Ultraviolet for a Meteorological Range of 26 km

of approximately 25 km. The derived surface ozone concentration of 1.8×10^{-3} cm/km is entirely reasonable and supports the short extrapolation.

In the visible and infrared windows, the measurements of Curcio, Knestrick and Cosden⁹ are sufficiently extensive so that they are able to present a series of aerosol attenuation coefficients, representative of a clear day with a meteorological range of 25 km, and which can be characterized by a continental aerosol with a particle concentration of about 200 per cc. This information is based on data acquired in the Chesapeake Bay area during the period April 1959 to January 1960. The aerosol attenuation derived from Reference 7, 8 combined with those contained in Reference 9 meet the requirements for values of $\beta_p(0)$ in Eq.(6). These coefficients as well as the Rayleigh attenuation coefficients for the wavelengths of interest are listed in Table 3.

TABLE 3. Rayleigh and aerosol attenuation coefficients at sea level for a meteorological range approximating 25 km

4.2 Aerosol Density at Sea Level

The measurements of Curcio *et al.*⁹ and Dunkelman and Baum^{7,8} were conducted at the same location and for approximately the same meteorological range, 25 km. An evaluation of the compatibility of the results of both investigations can be made by plotting β_p vs λ as shown in Figure 3. It is evident that the results are sufficiently compatible because of the character of the overall distribution. Since both field programs functioned at the same location and with very nearly the same meteorological range and since the results are sufficiently compatible, the aerosol number density at sea level for both sets of measurements is considered approximately equal. The aerosol number density at sea level $N_p(0)$ calculated by Curcio *et al.* approximates 200 cm^{-3} , which will be the value assigned to $N_p(0)$ in Eq. (6).

Figure 3. Aerosol Attenuation Coefficients at Sea Level

4.3 Aerosol Density as a Function of Altitude

Previously,¹ an aerosol number density distribution as a function of altitude, $N_p(h)$, was developed based on sea-level and altitude measurements. Briefly, field measurements of aerosol density variation with altitude, conducted between 1945 and 1952 and summarized by Penndorf²⁴ were used. This analysis shows aerosol number densities as having a scale height of 1.2 km to an altitude of 5 km. Balloon measurements of Chagnon and Junge²⁵ provide additional information concerning the vertical distribution of aerosols between 10 and 28 km. This information leads to the overall aerosol number density distribution shown in Figure 4. The distribution is used to provide the values for $N_p(h)$ at one kilometer intervals listed in Table 4 and used in Eq. (6).

The requirements for the right-hand side of Eq. (6) now are satisfied and an array of aerosol attenuation coefficients for a meteorological range of approximately 25 km can be computed for all altitudes and wavelengths of interest.

Figure 4. Representative Profile, Aerosol Number Density vs Altitude (see Table 4)

5. ATMOSPHERIC EXTINCTION

The term extinction is used to express more than one atmospheric attenuating component. In this section, three sets of extinction parameters are derived for each wavelength: extinction coefficients as a function of altitude, extinction optical thickness from sea level to a desired altitude, and extinction optical thickness from a desired altitude to space.

5.1 Extinction Coefficient vs Altitude

This is the sum of all the attenuating components,

$$\beta_{\text{ext}}(h) = \beta_r(h) + \beta_3(h) + \beta_p(h) \quad (8)$$

where

β_{ext} is the extinction coefficient as a function of altitude (km^{-1}),
 β_r is the Rayleigh attenuation as a function of altitude (km^{-1}),
 β_3 is the atmospheric ozone absorption coefficient as a function of altitude (km^{-1}),

and

β_p is the aerosol attenuation coefficient as a function of altitude (km^{-1}).

5.2 Extinction Optical Thickness from Sea Level to Altitude h

This parameter is expressed by

$$\tau_{\text{ext}} = \sum_0^h \bar{\beta}_{\text{ext}}(h) \cdot \Delta h \quad , \quad (9)$$

where

$\bar{\beta}_{\text{ext}}$ is the mean extinction coefficient (km^{-1}) for each altitude increment.

The altitude increment Δh was set at 1 km for these computations.

5.3 Extinction Optical Thickness from Altitude h to Space

The relationship is

$$\tau'_{\text{ext}}(h) = \tau_{\text{ext}}^{\infty} - \tau_{\text{ext}}(h) \quad . \quad (10)$$

$\tau_{\text{ext}}(\infty)$ is the optical thickness from sea level to space and its value is obtained by using Eq.(9) with the limits set between 0 and 80 km. Above 80 km $\int_{80}^{\infty} \beta_{\text{ext}} dh$ can be neglected.

6. EXPLORATORY CALCULATIONS

Some exploratory calculations for any of the wavelengths used are demonstrated readily by a few general cases.

6.1 Horizontal Transmission

For horizontal transmission (T_h) over a path (d) at any altitude (h), the extinction coefficient (β_{ext}) for that altitude is used,

$$T_h = \exp -[\beta_{\text{ext}}(h) \cdot d] \quad . \quad (11)$$

6.2 Vertical and Slant-path Transmission from Sea Level to Altitude h

For vertical and slant-path transmission (T_{0-h}), from sea level to some altitude, the extinction optical thickness (τ_{ext}) for that altitude is used, and

$$T_{0-h} = \exp -[\tau_{\text{ext}}(h) \cdot \sec \theta] \quad (12)$$

where

θ is the zenith angle.

6.3 Vertical and Slant-path Transmission Between Two Altitudes Above Sea Level

For vertical and slant-path transmission ($T_{\Delta h}$) between two altitudes above sea level, and from the geometry of Figure 5,

$$T_{\Delta h} = \exp - [\tau_{\text{ext}}(h_2) - \tau_{\text{ext}}(h_1)] \sec \theta \quad (13)$$

where

$\tau_{\text{ext}}(h_1)$ is the extinction optical thickness at h_1 ,

and

$\tau_{\text{ext}}(h_2)$ is the extinction optical thickness at h_2 .

Figure 5. Geometry for Transmission Between Two Altitudes, h_1 and h_2

6.4 Vertical and Slant-path Transmission from Altitude h to Infinity

For vertical and slant-path transmission ($T_{h-\infty}$) from altitude h to infinity, the extinction optical thickness (τ'_{ext}) is used,

$$T_{h-\infty} = \exp - [\tau'_{\text{ext}}(h) \cdot \sec \theta] . \quad (14)$$

7. CONCLUDING REMARKS

The tabulations that follow can be considered as a model for atmospheric attenuation and ozone absorption to 50 km. The atmospheric coefficients and optical thickness values represent a clear standard atmosphere with 0.35 cm total ozone.

Parameters for Rayleigh attenuation are included since they are widely used. The format deals systematically with a multiplicity of variables thus permitting many kinds of exploratory calculations. It is expected that as additional knowledge is acquired, revisions may be necessary. For the present the tabulations conform to the best available information.

8. TABULATION OF PARAMETERS

TABLE 5.1. Parameters at 0.27 microns

Alt (km)	Rayleigh atten. coeff. (km ⁻¹)	Rayleigh optical thick. (0-h)	Rayleigh optical thick. (h-∞)	Aerosol atten. coeff. (km ⁻¹)	Ozone absorp. coeff. (km ⁻¹)	Ext. coeff. (km ⁻¹)	Ext. optical thick. (0-h)	Ext. optical thick. (h-∞)

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

All exponential numbers are designated by a sign following the number, then by two zeros and the exponent. Thus, 3.26-003 = 3.26×10^{-3} .

Acknowledgments

The writer wishes to express appreciation to W.S. Hering, S. Penn, and T.R. Borden, Jr. for the helpful discussions pertaining to recent ozone measurements, and to R. Penndorf and R.G. Walker for their helpful suggestions when reviewing this material.
