EFFECT OF SULFURCUS COMPOUNDS ON THERMAL STABILITY AND CORROSIVE PROPERTIES OF FUELS FOR TURBOCOMPRESSOR AIR-REACTIVE ENGINES

P. I. Davrdov and G. F. Bol'shakov

In the fuel system of an engine the fuel may be subjected to changes, leading to deterioration of its exploitation properties.

One of the factors, deteriorating the exploitation qualities of a fuel in the fuel system of an engine, appears to be the rise in temperature.

In jet engines the fuel is heated in pumps to $20 - 30^{\circ}$ and in fuel oil radiators - by 30 to 40° more. The fuel system as a rule, is mounted in the body of an air compressor, the temperature of which reaches in certain parts $200 - 2^{\circ}0^{\circ}$, which causes additional hearing of the fuel.

Alreay in transport aircraft with turbojet engines of aircraft type TU-104, at cruising velocities of 800 - 1000 km/hr, there is observed a noticeable heating of the fuel.

Calculations show, that at a long last aircraft flight, at a speed of 1800 - 2000 km/hr, the temperature of the fuel will constitute 80° in the fuel tank, at the output from the oil radiator $130 - 150^\circ$ and in the fuel pump 140 -160°.

FTD-TT-65-1276/1+2+4

]

In these conditions the fuel oxidizes intensively - tarry compounds and insoluble compounds are formed, plugging up the filters and depositing themselves in various parts of the fuel system. At higher temperatures the fuel being actively to corode the metals of the fuel system, especially copper alloys.

Formation of a residue accelerates at a temperature rise to $150 - 160^{\circ}$; and with further temperature rise - it decreases. Tar formation and corrosion action also have a maximum in the area of temperatures of the order of $170 - 180^{\circ}$.

An exclusive great value for corrosion processes of nonferrous metals of the fuel system and residue formation have sulfurous compounds. This is pointed out by the increase in sulfur content in the residue, comparative with its content in the fuel and the increase in the fraction of the metal in residue, in proportion to the increase in content of sulfurous compounds in the fuel.

The investigations carried out by N. N. Torichnev have established, that alkane-cyclane fractions, separated from standard fuels TS-1, T-1 and T+5, do not contain sulfurous compounds and show no corrosive effect on bronze when heated to 150° for a period of 6 hours; in these fractions no residues form.

When adding to these fractions 0.08% (in conversion into sulfur) butylsecondary octyl-sulfide in these conditions, 2.6 mg/100 ml of residue (sedimentation) is formed and corrosion of the bronze is observed (0.7 g/m^2). admixtures of diisoamylsulfide and dibutyldisulfide mixtures act somewhat more intensive.

Sulfurous fuel compound's are concentrated in its tarry and heavy aromatized part. Therefore, the detarring and dearomatization of fuels leads to a slowing

Ż

FTD-TT-65-1276/1+2+4

down of corrosion processes and to a slowing down in residue formation during their heating. Together with our reports it has been revealed, that during the heating in the above mentioned conditions of aromatic fuel fractions, desorbed from silica gel with benzene and desulfurized, residue deformations are observed. Even a pure a-methylnaphthaline during heating for a period of six hours, separates a residue in the amount of 1-2 mg/100 ml.

These investigations have shown, that the basic corrosion and residue formin agents appear to be sulfurous compounds of fuels and, in a known measure, ingrelic aromatic hydrocarbons.

For a more detailed investigation of the effect of individual groups of sulfurous compounds on the corrosion of metals of the fuel system, the formation of residues in fuels during their thermal treatment, experiments were made with separation from fuels and with individually synthesized sulfurous compounds.

TC-1 fuel was taken for the investigation, obtained from petroleum from the Devonian horizon of the Mukhanovsk petroleum industry, subjected to hydro-purification at the installation of the Novo-Kuybyshev petroeum refining plant (experimental batch). The fuel contained 0.01% of general sulfur; mercaptanes were not discovered in the fuel. Individual sulfurous compounds and sulfurous fractions were added to this fuel, separated from TC-1 fuel and DA-Diesel fuel in an amount close to the content of sulfur in standard fuels.

Individual sulfurous compounds were presented to us by the Bashkir branch of the Academy of Sciences USSR. Sulfur and nitrogen containing individual compounds, were synthesized by F. Yu. Rachinskiy.

FTD-TT-65-1276/1+2+4

Separation of fractions of natural sulfurous compounds from the fuels was realized by the lab of Prof. R. D. Obolentsev by the absorption method, with subsequent extraction of acetic acid murcury through mercury complexes and by additional pruification with picric acid.

In the composition of natural sulfuric compounds, separated from TC-1 fuel, included are preferably alphatic and aromatic sulfides, and also a certain amount of residual sulfur.

Sulfurous compounds, separated from Diesel fuel DA, contained 50% sulfides, 7 - 10% of disulfides and 40 - 43% of residual sulfur.

The basic physico-chemical properties of sulfurous compounds are listed in Table 1.

The investigation method was reduced to the following. The tested fuel in the amount of 150 ml was poured into the cylindrical vessel made from 12KHN3A steelwith a volume of 300 ml. Suspensions (g_1) were preliminarily placed in the fuel, a bronze plate from VB-24 with a total surface of >0 cm². After filling the vessel was hermetically covered and kept at 150° for a period fo six hours at continuous mechanical mixing (or account of oscillatory motion of the vessels).

After completion of the experiment, the fuel was cooled to room temperature and filtered through a glass filter No. 4. The residue was washed with petroleum ether and suspended. In the filtrate the acidity of the potentiometric method and the optical density were determined.

FTD-TT-65-1276/1+2+A

The bronze plate was washed with petroleum ether, dried in the air and suspended (G_2) . The plate was then washed with an alcohol-benzene mixture (1 : 1), dried and again suspended (G_3) .

The amount of depositions, insoluble in fuel, was calculated by the difference ence. G_2-G_3 in σ/m^2 . Corrosion of the bronze was determined as the difference G_1-G_3 in g/m^2 .

Ē

Investigation results of the effect of sulfurous compounds on the corrosion properties and thermal stability of hydropurified TC-1 fuel are given in Table 2.

From the given data it is evident, that aliphatic mercaptanes in fuel at 150° cause sharp corrosion in bronze and intensify the condensation oxidizing reaction with the formation of soluble tars (increase in optical density), of tarry deposits on the metal and insoluble residue in the fuel.

Corrosion processes and oxidizing condensation processes become intensified with the increases in mercaptan content in the fuel. An increase in mercaptan content from 0.005*) to 0.01% intensifies corrosion by almost 9 times, residue formation - by 3 more times.

The forming insoluble residue contains sulfurous corrosion products of copper and of processes of deep oxidizing condensation of the fuel.

Pronze plates after being affected by fuel, containing mercaptanes, have a nonuniform, corroded surface (Figure 2). In Figure 1, for comparison, is shown a bronze plate after being affected by hydropurified fuel without mercaptanes.

The negative role of aliphatic mercaptanes appears also in the mixture with sulfurous compounds, separated from fuel. When 0.25% of these sulfurous compounts without mercaptanes are added to hydropurified fuel corrosion of bronze rose in double, residue formation - by 1.6 times, and when 0.24% of sulfurous compounds of 0.61% of secondary octylmercaptan was added to this fuel, corrosion rose b- 7.5, and residue formation - by five times. Microphotography of the plate after being affected by hydropurified fuel with an addition of 0.24% of

* In this case and in subsequent ones, the content of sulfurous compounds are expressed in weight % of sulfur in the fuel.

sulfurous compounds and 0.01% of octylmercaptan is shown in Figure 3.

FTD-TT-65-1276/1+2+4

FTD-1T-65-1276/1+2+4

Mercaptothiosoline in concentration of 0.02% does not raise the corrosion of bronze and residue formation.

In this way, the properties of mercaptanes depend upon the structure of the radical. Aliphatic mecaptanes sharply intensify the corrosion properties of the fuels and reduce their ttermooxidation stability. Combined presence of thiol, amine and phenyl groups improv the anticorrosion properties.

Addition to the hydropurified fuel TC-1 of 0.05% of individual sulfides, has practically no effect on its corrosiveness and thermal stability. At an increase in the number of sulfides to 0.15% there is observed a noticeable increase in bronze corrosion, tar and residue formation.

Disulfides show a somewhat better effect on the exploitational characteristics of fuels in comparison with sulfides of the very same structure. Thiophanes and thiophenes are little different from sulfiess; the very same rules appear. connected with their structure.

When adding 0.01% of aliphatic mercaptan to fuels, containing 0.04 and 0.14% of aliphatic sulfide and aliphatic disulfide mixture, corrosion of bronze and residue formation rise by 2.2 - 2.8 times, which again confirms the special activity of aliphatic mercaptanes. It should be mentioned, that corrosion processes of bronze, residue and tar formation in fuels change upon the addition of sulfurous compounds in one direction: if metal corrosion is intensified, then the oxidizing condensation processes are intensified simultaneously. The which are/ action of fractions/separated from TC-1 fuel and Diesel fuel DA of natural sulfurous compounds on the properties of yet fuels investigated by us is analogous

Q

FTD-TT-65-1276/1+2+4

to the average effect of sulfides, disulfides and thiophenes. Consequently, the properties of synthesized sulfurous compounds from the investigated viewpoint, correspond approximately to properties of sulfurous compounds, contained in fuels.

Conclusions

1. Aliphatic cercaptanes, contained in fuel as a result of long-lasting. heating of same at 150°, cause sharp corrosion of bronze and formation of tars and insoluble residue. It is necessary to reduce the mercaptan content in fuel.

2. The investigated sulfurous compounds, by their corrosive effect on metals and the effect of tar and residue formation processes in fuels during their heating to 150°, are divided into the following descending series: mercaptanes, disulfides, aliphatic sulfides, aromatic sulfides, thiophanes.
