Abstract

Low dispersion spectra ($\approx 10,000 \text{ \AA/mm}$) have been obtained of the brighter members of the Hercules Cluster and Abell #2197 and 2199. The survey identifies the reddest and bluest galaxies in each cluster. Color-magnitude diagrams are drawn for each cluster.

Introduction

The preceding paper (Philip and Sanduleak, 1969) describes the crossed-prism survey of clusters of galaxies. This paper surveys galaxies in the Hercules Cluster and two clusters in Abell's catalogue (1958), numbers 2197 and 2199.

Observations

The observational data was obtained from two plates taken with the Warner and Swasey Observatory Schmidt telescope. The plates are listed in Table 1.

Table 1
Crossed Prism Plates
Warner and Swasey Observatory

Plate #	Object	R A (1962)	Dec	Emulsion	Exposure	Date	Remarks
6592	Hercules Cluster	16 03	17 54	IN	60 ^{min}	5 29/30 1962	
6595	Abell #2197,2199	16 27	39 48	IN	75 ^{min}	5 29/30 1962	Red end of spectra slightly out of focus.

The galaxies measured in the Hercules Cluster were listed in Table 2. The NGC number (or I.C. number if the number is followed by an asterisk) is listed in column 1, the right ascension and declination (1950) in columns 2 and 3, the composite color index in column 4 and remarks in column 5. All galaxies, to mag. = 15.5, from Zwicky and Herzog (1963) that fall in the area of the plate taken of the Hercules Cluster are listed in Table 2. Those galaxies without an index are followed by an explanatory remark in the remarks column.

The galaxies measured in Abell 2197, 2199 are listed in Table 3, following the same format as in Table 2. The positions and magnitudes are taken from Zwicky and Herzog (1966).

Discussion

The color-magnitude diagram for the Hercules Cluster is presented in Figure 1. The diagram resembles that of the Coma Cluster, in that the brightest galaxies have the same spectral index, and the fainter galaxies have redder and bluer indices. There is another plot to the right of the Hercules C-M diagram which shows the C-M diagram for galaxies outside the immediate area of the cluster. In appearance this plot is very different, being merely

a scatter diagram, and is probably the result of the majority of these galaxies being field galaxies. In Figure 2 is shown a plot of the positions of the cluster galaxies. Solid triangles indicate the 8 reddest galaxies, hollow circles indicate the 6 bluest galaxies; and solid circles indicate the position of the remaining galaxies. As was noted in the Coma Cluster, the blue galaxies seem to be somewhat more centrally condensed in the cluster than do the reddest galaxies which are spread over a larger area of the celestial sphere.

The galaxies measured in Abell 2197 and 2199 are plotted in a color-magnitude diagram in Figure 3. In Zwicky and Herzog (1966) these two clusters are marked as cluster #12 on page 188. Figure 3 is divided into three sections. The first, on the left, plots all the measured galaxies that fell within the boundary marked in Zwicky and Herzog (1966) for cluster 12. The next two sections plot the color-magnitude diagram for the clusters Abell 2197 and 2199. The contours of these clusters were transferred from a chart in Clark (1968) showing isopleths for each cluster. The isopleths representing 990 galaxies per square degree close on themselves and ~~this isopleth was~~ ^{these isopleths were} transferred to the chart in Zwicky and Herzog to decide which galaxies would be chosen as belonging to each cluster. Only the brightest $1\frac{1}{2}$ magnitudes of the cluster members are being sampled in the color-magnitude diagrams. The diagrams for 2197 and 2199 are quite similar, in spite of the low statistical sample of galaxies in each diagram. The diagrams resemble that for the Coma Cluster more than that for the Virgo Cluster, therefore Abell 2197 and 2199 can be classified as regular clusters. A plot of the positions of the bluest and reddest galaxies in each cluster does not reveal any information due to the small number of galaxies in each sample. The galaxy

at $\alpha = 16^h 26^m.8$, $\delta = 41^\circ 20'$ is the bluest galaxy in either cluster. The image is diffuse, but it can definitely be classified as a blue object.

It should be noted that the indices from plate #6595 are much redder than those from the other plates. This occurs because the red ends of the spectra on this plate were slightly out of focus, thus making the red end appear more heavily exposed. The ordering of the galaxies by color is not disturbed by this effect.

It is hoped that further plates can be obtained of clusters within 100 mpc of the sun, such as the Perseus and Ursa Major Clusters. I wish to acknowledge the support of the Office of Naval Research.
