FOREWORD

This report was prepared by Dynatech R/D Company under Contract No. F33657-70-C-1156 to the Aeronautical Systems Division, Life Support System Program Office, Endeavor Number AO117, Wright-Patterson Air Force Base, Ohio. The work was administered by the Nonmetallic Materials Division, Air Force Materials Laboratory, Directorate of Laboratories. Mr. Robert M. Stanton and Mr. Stanley Schulman were project engineers.

This report covers work conducted from June 8, 1970 to November 16, 1971. Dynatech Report Number: 1022.

The program was directed by Mr. Ralph L. Wentworth. Technical supervisor of the program was Mr. Kenneth R. Sidman. Physical testing and polymer evaluation was supervised by Mr. John B. Gregory. Assisting in the evaluation of candidate reagent systems and the set-up of the fabric treatment facility were Mr. Glenn K. Armstrong, Dr. Shafik E. Sadek, and Mr. William H. Crandell. Consultants to the project team were Prof. P. L. T. Brian and Prof. J. Baldwin.

Publication of this report does not constitute Air Force approval of the report's findings or conclusions. It is published only for the exchange and simulation of ideas.

13. ABSTRACT

Textiles composed of polybenzimidazole (PBI) fibers combine superior qualities of non-flammability and comfort with functional utility. A further improvement desired in the qualities of PBI fabric is reduction of its tendency to shrink when exposed to flame and high temperature. Such shrinkage on exposure of an individual to a fire may bring the fabric of a garment in more intimate contact with the wearer. Elimination of the tendency to shrink would reduce the rate of heat transfer to a wearer, prolonging the period of protection in a fire exposure situation. The work reported here was undertaken to develop a treatment for PBI which stabilizes it with respect to thermal shrinkage.

Chemical treatment of PBI fiber or fabric which introduces chemical bonds between the basic polymer chains of PBI was found to stabilize PBI against thermal shrinkage. Among such treating agents examined a treatment involving immersion of PBI in a liquid mixture of 5% chlorosulfonic acid in phosphorous oxychloride followed by heating and neutralization was found to be satisfactory. Fabric so treated is resistant to thermal shrinkage yet unchanged in strength and nonflammability. The treatment is stable to laundering.

Woven PBI fabric was treated by the process developed. Following demonstration of the adequacy of this fabric, a pilot processing line for treating PBI tow was constructed. PBI tow treated on this pilot line was converted into fabric for evaluation.

As a result of this work, a functionally acceptable process for reducing the thermal shrinkage of PBI fiber has been developed. It is recommended that further investigation of the tow treatment process be conducted in order to attain improved balance of the color and fabric properties of treated material.

ABSTRACT

Textiles composed of polybenzimidazole (PBI) fibers combine superior qualities of nonflammability and comfort with functional utility. These characteristics qualify PBI fabric especially well for service in Air Force garments such as flyer's suits and coveralls. A further improvement desired in the qualities of PBI fabric is reduction of its tendency to shrink when exposed to flame and high temperature. Such shrinkage may bring the fabric of a garment in more intimate contact with the wearer, thus increasing the rate of heat transfer to the individual from a flame source. Elimination of the tendency to shrink would reduce the rate of heat transfer to a wearer, prolonging the period of protection in a fire exposure situation. The work reported here was undertaken to develop a treatment for PBI which stabilizes it with respect to thermal shrinkage.

Chemical treatment of PBI fiber or fabric which introduces chemical bonds between the basic polymer chains of PBI was found to stabilize PBI against thermal shrinkage. The effectiveness of a number of such treating agents and the coincident effects on other fiber properties were determined. A treatment involving immersion of PBI in a liquid mixture of 5% chlorosulfonic acid in phosphorous oxychloride followed by heating and neutralization was found to be satisfactory. Fabric so treated is resistant to thermal shrinkage yet unchanged in strength and nonflammability. The treatment is stable to laundering.

Woven PBI fabric was treated by the process developed. Following demonstration of the adequacy of this fabric, a pilot processing line for treating PBI tow was constructed. PBI tow treated on this pilot line was converted into fabric for evaluation.

A functionally acceptable process for reducing the thermal shrinkage of PBI fiber has been developed. It is recommended that further investigation of the tow treatment process be conducted in order to attain improved balance of the color and fabric properties of treated material.

SUMMARY

Polybenzimidazole (PBI) fibrous structures exhibit stability to high temperature oxidation, excellent textile physical properties, and high moisture regain. However, when subjected to flames PBI fabrics tend to shrink. Work at Dynatech R/D Company under contract for NASA-MSC improved both the thermal and oxidative resistance and dimensional stability of PBI fabric. An optimization of the vapor treatment was undertaken for the Aeronautical Systems Division, Life Support System Program Office ASWL, Wright-Patterson Air Force Base.

Reagent systems other than the vapor phase treatment of PBI with phosphoryl chloride proved to be superior, and treatment of fabric with 5% chlorosulfonic acid in phosphorus oxychloride proved to be outstanding. Seven yards of fabric were treated by this process and submitted to the Air Force Material Laboratory for evaluation. This fabric met the target requirements: exhibiting less than 10% thermal shrinkage in a test of exposure for seven seconds to a controlled Meker burner flame, less than 10% shrinkage on treatment, no reduction in tensile strength, and flammability essentially the same as the untreated fabric. The treatment was stable to prolonged rinsing in alkaline solutions and washing in alkaline soap solutions.

In Phase II of the program the chlorosulfonic acid treatment was converted to a continuous process to treat PBI tow. A pilot processing line capable of treating approximately one pound per hour of PBI tow was constructed. Process variables were adjusted on this line until a combination of tow properties including low thermal shrinkage, good color, and high tensile strength was achieved. Thirty pounds of treated tow were prepared and converted into fabric for evaluation.

It is recommended that development work on the treatment of tow by this process be extended to include the investigation of other parameters which could not be examined under the scope of this program. It is anticipated that the material and specifications developed in such an investigation will enable the attainment of the balance of color and fabric properties necessary for Air Force textile material.

Section 2

INTRODUCTION

2.1 Background

As a result of the interest of the Department of the Air Force in developing a chemical treatment of polybenzimidazole (PBI - specifically, 2,2' (m-phenylene) -5, - (6,6' -bibenzimidazole)) fibrous structures to effect a superior nonflammable, thermally stable, and nonshrinking material, Contract No. F33657-70-C-1156 was awarded to Dynatech R/D Company. The primary emphasis of this work was to be the optimization of vapor phase treatment of PBI with phosphoryl chloride to effect a thermal stabilization of the fiber. A two phase investigation was proposed - the first phase consisting of the research and development of the treatment method and the second concerned with scale-up of the process to treat quantities of material.

2.1.1 Scope

As the investigation progressed, it became apparent that the phosphoryl chloride treatment was not exceptionally effective in stabilizing fibrous structures of the polymer. Consequently, the study was broadened to include the investigation and optimization of other reagent systems that provide thermally stable crosslinks between polymer chains. The crosslinks were intended to restrict the polymer chain mobility so that the highly strained, anisotropic chain configuration produced by the fiber drawing would not relax when heated.

2.1.2 Technical Discussion

Polybenzimidazole fibers have tremendous potential value in the manufacture of nonflammable clothing - they exhibit the flexibility, drape, surface characteristics, moisture regain and physical properties known to determine comfort. In addition, they are self-extinguishing in environments containing less than 35% by volume oxygen (for fabric conditioned at 70° F and 65% relative humidity). The present PBI fibers, however, exhibit thermal shrinkage in the brief exposure, high intensity heat of the open pit flame test. This shrinkage is apparently due to a relaxation of the polymer chains.

Two methods present themselves for minimizing thermal shrinkage. One involves preshrinking the fabric through chemical or heat treatment so that the resultant cloth exhibits a very low thermal shrinkage. The other involves reducing the mobility of the polymer chains.

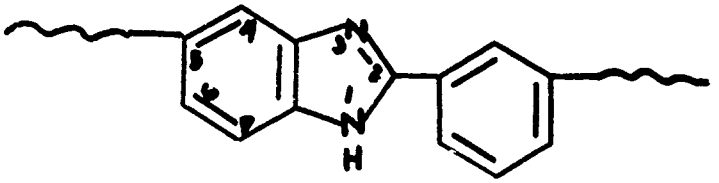
The PBI fibers may be preshrunk through the use of chemical agents able to swell and plasticize the polymer. In this case the swelling agent enhances chain mobility and permits the polymer molecules to reorient themselves to relieve the strain. The same relaxation may be achieved by heating the fibers. In either case, a decrease in tensile strength occurs because the anisotropic, strained configuration contributing to the fiber strength is lost.

To reduce chain mobility, crosslinks may be introduced along the polymer chain in sufficient number so that these bonds will connect the individual polymer molecules into a three-dimensional network. Such a network greatly restricts the fiber shrinkage. In this approach the tensile strength of the fiber is retained.

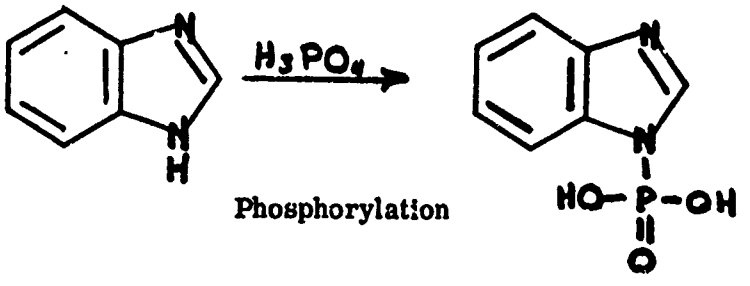
Crosslinks may be introduced into the fiber thermally or chemically. Thermal crosslinking of certain polybenzimidazoles was described by Plummer and Marvel (Ref. 1). They found that heating the polymers under vacuum at temperatures exceeding 300° C tended to change the yellowish compounds to a brownish-black form that was insoluble in all solvents. The conversion of the aromatic rings to diphenyl groups was discussed as a possible crosslinking mechanism. In oxygen-containing atmospheres, temperature above 350° C have been reported to induce crosslinking. In these cases also, a reduction in polymer solubility was taken as evidence of crosslinking behavior. Shulman and Lochte reported (Ref. 2) that at pyrolysis temperatures between 450° C and 500° C crosslinking of PBI occurs via amide interchange or bisphenyl coupling.

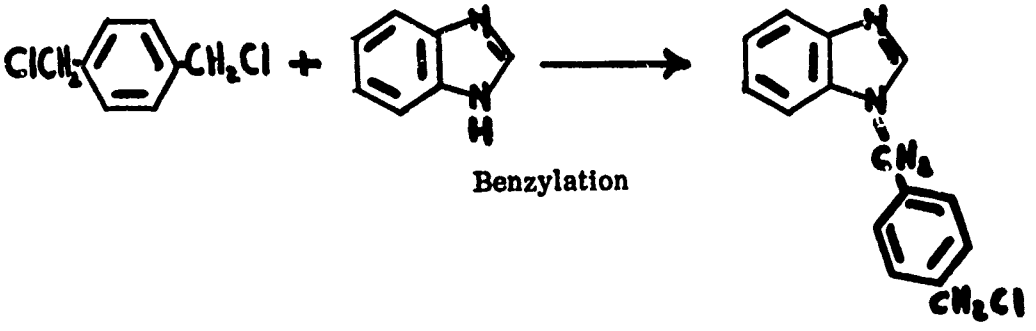
Chemically, crosslinks may be introduced through the incorporation of any moiety on the polymer chain that will bridge across chains. The 1- and 3-positions of the benzimidazole ring and the aromatic moieties are particularly susceptible to attack. Consequently, multifunctional agents selected on the basis of their reactivity with these sites, offer promise as potential crosslinking agents.

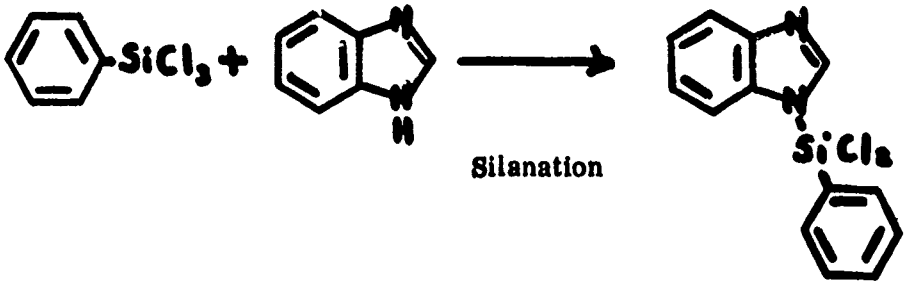
The site-numbering system is as follows:

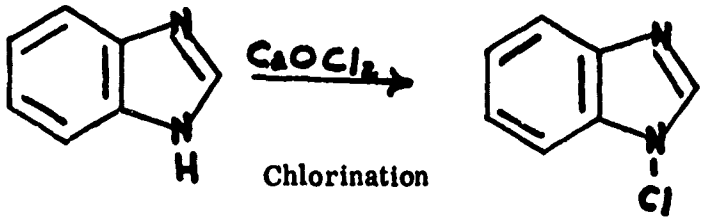


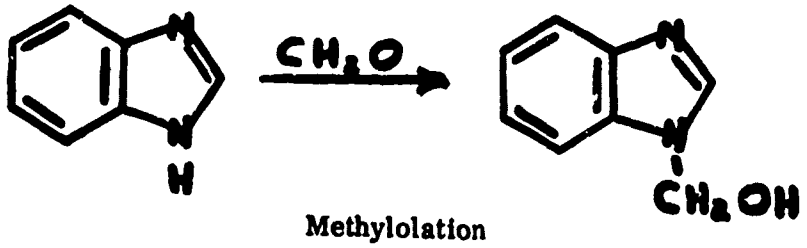
From a review of the chemistry of benzimidazoles (Ref. 3), it is possible to identify a number of candidate reactions. The imidazole ring, for example, may be attacked by phosphorylating, silanating, chlorinating, and methylolating agents.





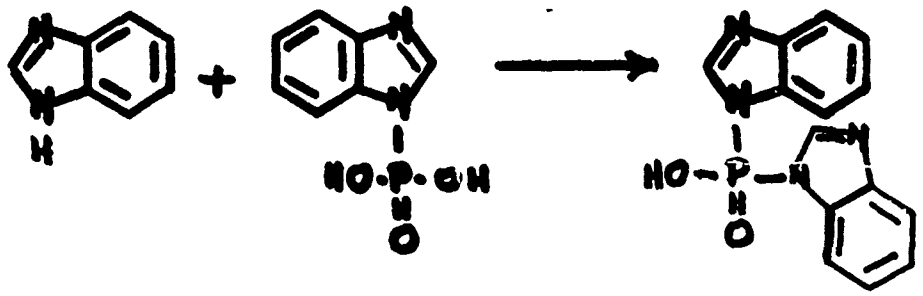




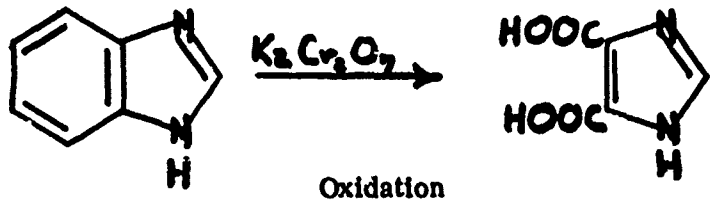


Methylolation

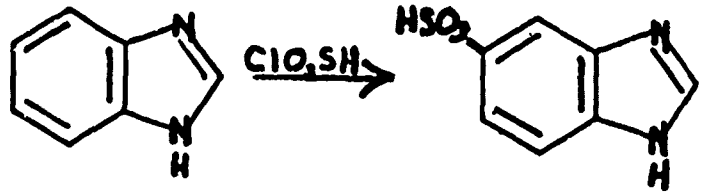
These agents may crosslink through imidazole rings. For example,



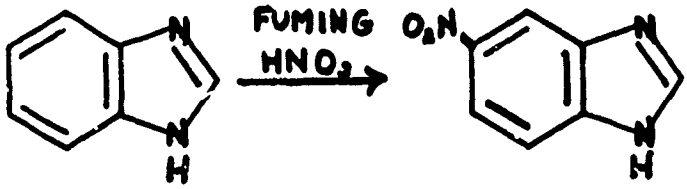
Oxidizing, sulfonating, nitrating, acylating, and free-radical generating agents have been shown to attack aromatic nuclei. For example,



Oxidation

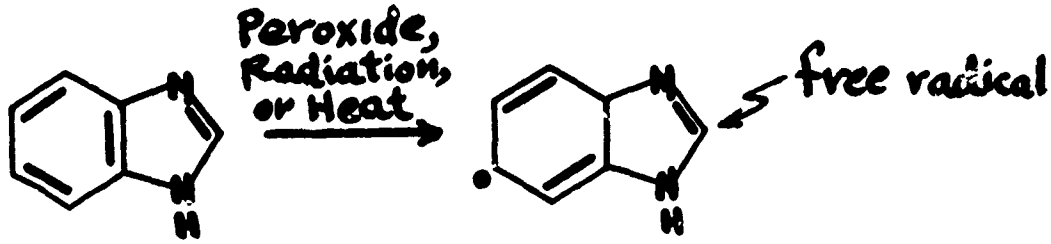


Sulfonation



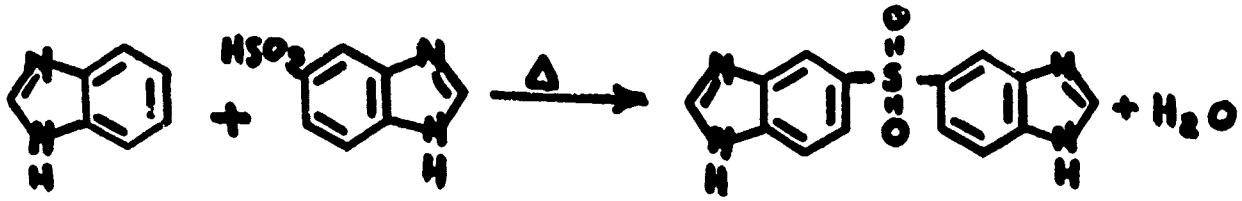
Nitration

Acylation



Free-Radical Generation

Crosslinking may then occur either between aromatic rings



or between an aromatic and an imidazole ring.

The effectiveness of the crosslinking is measured with respect to improvements in fabric dimensional stability while at the same time maintaining desirable textile properties.

2.2 Method of Approach

In Phase I of the program two experimental approaches were undertaken. The first involved an extension of the $POCl_3$-oxygen, vapor-phase treatment developed for NASA-MSC under Contract NAS 9-8179. The second approach consisted of a search for and optimization of crosslinking agents which dimensionally stabilize PBI fibrous structures.

Treatments were evaluated first for effectiveness in reducing the thermal shrinkage of fabric samples. If shrinkage behavior was found to be improved then the durability of the treatments to laundering was evaluated. If they passed these two examinations, the treated fabrics were examined for color, hand and drape, flammability, and moisture regain.

The goal of this first phase of the contract was to produce a treated fabric with less than 20% thermal shrinkage by the end-use application test of the Air Force Materials Laboratory, less than 30% fabric shrinkage on treatment, less than 25% reduction in tensile strength, and flammability essentially the same as the untreated fabric.

In Phase II of the program the feasibility of the process developed in Phase I was evaluated for treating PBI in the form of fabric, yarn, staple, fiber, and spinning dope. The advantages and disadvantages of treatment in the various forms are summarized in Table I. On the basis of this analysis, it was decided to treat PBI tow.

A tow treatment facility was established on which the process variables were adjusted to give the best combination of low thermal shrinkage, good color, and high tensile strength.

Thirty pounds of PBI were then processed to provide a sufficient quantity of treated cloth for end-item tests in full scale open-pit flame trials.

Table I

The Advantages and Disadvantages of Treating PBI in Various Forms

PBI Form Treated	Advantages	Disadvantages
	- Uniform treatment of PBI ensured regardless of form of end item and end item precursors.	- Changes in PBI reaction conditions, spinning conditions, and drawing conditions would be required
Spun and drawn fiber	- Uniform treatment of PBI ensured-independent of end item. - No change required in present PBI processing techniques. - Applicable to proposed 1-2 million lb/yr facility producing fiber and tow.	- Changes in fiber handling and processing equipment may be required to adjust for changes in surface characteristics and denier of fiber
Staple	- Fiber may be processed through to staple with no change in equipment settings or equipment. Batch processing possible.	- Not applicable to continuous filament processing. - Changes in staple handling and processing equipment may be required.
Yarn	- PBI may be processed through to staple with no change in equipment setting or equipment.	- Changes in present yarn handling and processing equipment may be required. - Changes in chlorosulfonic acid process reaction conditions will be required depending on weight of yarn.
Fabric	- Fiber may be processed into end-item-no dislocation of any PBI processing step is necessary.	- Chlorosulfonic acid process would have to be modified for various weaves, weights, and widths of fabric.

Section 3

PROCEDURES AND RESULTS

3.1 Phase I - Experimental

The experimental fabric treatments discussed in this report were conducted in four types of reactors - one constructed of stainless steel, two of glass, and one of stainless steel and glass. The 316 stainless steel reactor, a Benco Model 150-E equipped with a gas sparge tube, dual heating mantles, condenser, and pressure gauge, is shown in Figures 1 and 2. The Benco stainless steel reactor was used to evaluate phosphorus oxychloride vapor phase reactions at elevated temperatures and pressures. Glass Reactor #1, consisting of a 4000 mℓ beaker heated by a hot plate and covered by a 2000mℓ round flask to serve as an air condenser, was used to evaluate treatments involving fabric immersion. Glass Reaction #2, consisting of a 2000mℓ resin reaction kettle, Scientific Glass Company Catalogue Number J4401, equipped with an electric heating mantle, oxygen sparge tube, and a condenser, was used to conduct reactions in the vapor phase under reflux conditions. A reactor constructed from 310 stainless steel and Pyrex glass was used to process continuously the seven square yards of fabric submitted to the Air Force Materials Laboratory in fulfillment of one of the contract requirements of Phase I. This continuous fabric treatment reactor, which was the prototype for the tow treatment facility in Phase II, described in detail below.

3.1.1 Continuous Reactor

A pilot scale treatment facility was constructed to evaluate the critical elements in the continuous process. A seven inch 316 stainless steel pipe was used as the reactor. Heat lamps were set up before and after the reactor to dry the fabric and vaporize excess phosphorus oxychloride, respectively. A motorized take-up roll with variable speed control was used to vary the residence time of the fabric in the reactor. A Schematic diagram of the pilot facility is given on page 13. Following treatment of a web of fabric in the pilot facility, the roll of fabric was unwound and draped in an air circulating oven at 300° C for varying periods in order to complete the treatment.

Path of Fabric

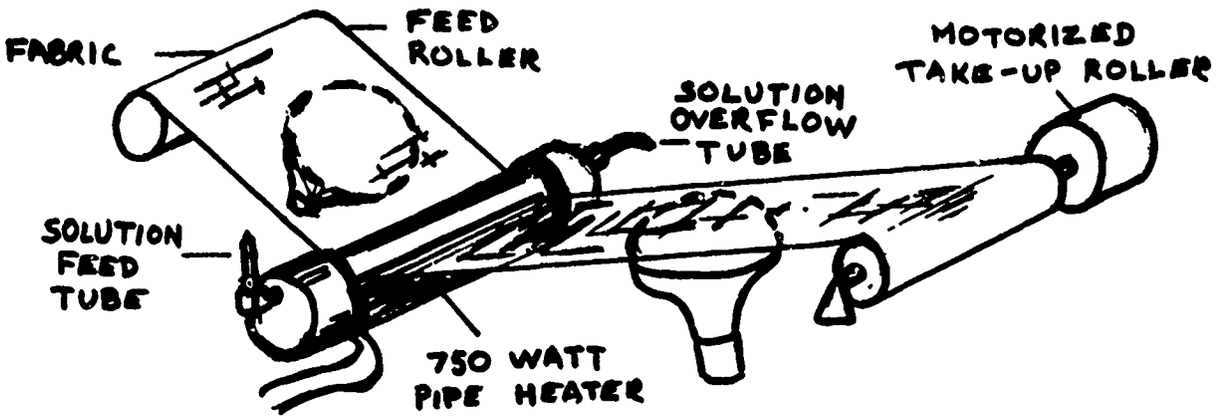

Figure 4. Schematic Diagram of Pilot Scale Treatment Facility

The pilot reactor was scaled up to treat a 46 inch wide fabric swatch. From the pilot work it was found that contact between layers of the fabric on the take-up roll caused discolorations and stiffening in the contact areas. To remedy this, polyethylene film was inserted between each layer. The full scale unit is shown schematically below and is pictured in Figure 3.

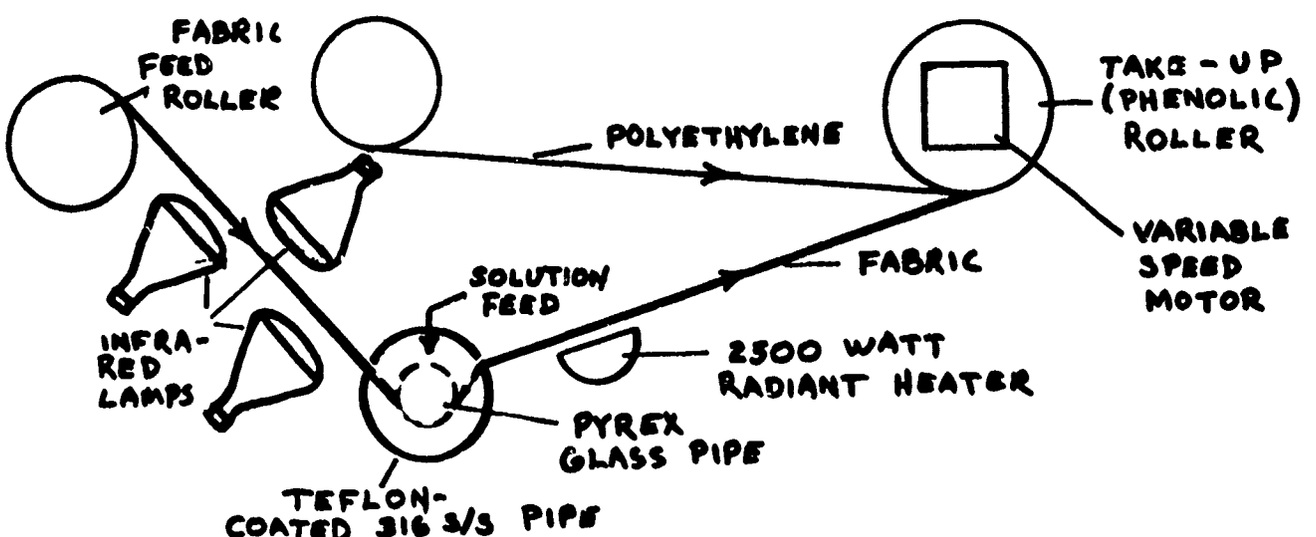

Figure 5. Schematic Diagram of 46-Inch Wide Treatment Facility

3.1.2 Chemicals

Reagent grade chemicals were used in the experiments except where otherwise noted.

3.1.3 Polybenzimidazole Fabric

The physical properties of the fabrics used in Phase I are given in Table II. The method for testing for fabric shrinkage during flame impingement is given in Appendix A.

3.1.4 Study of Effectiveness of Various Treatments

The study of treatments of the reduction of thermal shrinkage of polybenzimidazole fabric is summarized in Tables IV and XI.

3.1.5 Preparation of 7 Yards of Fabric Using Optimum Conditions

Table XII gives the details of the fabric treatment procedure and the physical properties of the fabric before and after treatment.

3.2 Phase II - Experimental

3.2.1 Apparatus

The pilot facility for the treatment of PBI tow is shown in Figure 4.

3.2.2 PBI Tow

In the process evaluation experiments 550 fil (1.5 denier/fil) fiber was plied to 16,500 fil tow. To prevent the tow from expanding as it passed over rollers in the process line, a twist of 1.5 turns/inch was incorporated into the tow.

In the production of 30 lbs of treated fiber, 5000 fil tow, plied to 15,000 fil and twisted 1.5 turns/inch was utilized.

The tow was treated in the as received condition - the lubricating oils were not removed prior to processing.

The physical properties or the fiber used in the process evaluation experiments are given in Table III.

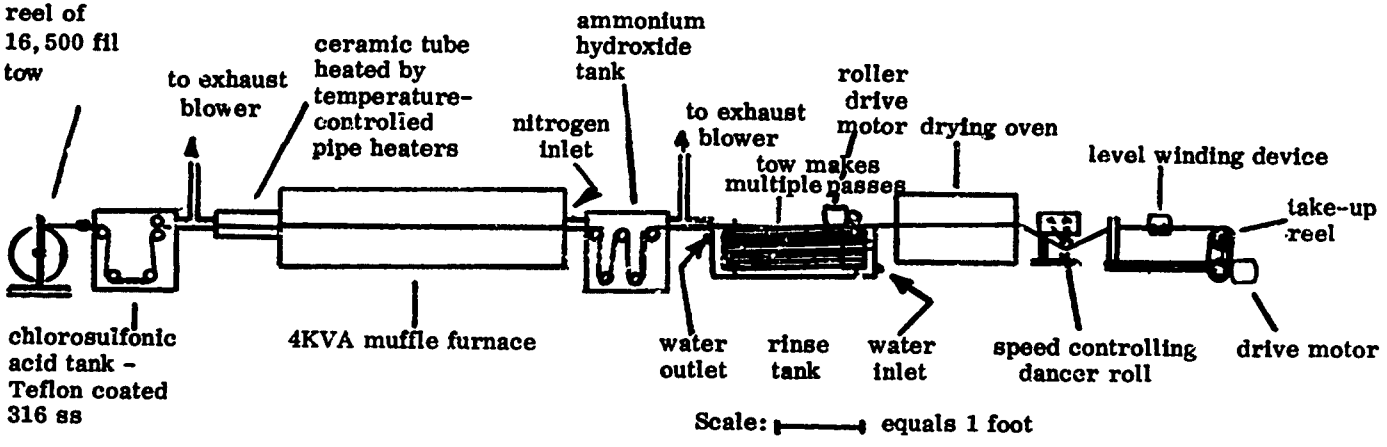

Figure 6. Processing Facility for the Application of the Chlorosulfonic Acid Stabilization Treatment to PBI Tow

3.2.3 Chemicals

Technical grades of chlorosulfonic acid (duPont) and phosphorus oxychloride (Hooker) were used in Phase II processing.

Notes

(1) Samples received from Air Force Materials Lab (AFML) on 6 July 1970, approx. 3 yds^2 of 6-1 and 4 yds^2 of 6-2.
(2) Fed. Test Method Std. 191, Method 5040, full width short specimen method.
(3) Dry cleaned for 45 minute cycle in a coin operated dry cleaning machine.
(4) Washed in 8 lb. commercial coin operated washer with reciprocating agitator for full cycle through spin dry, using hot water and 38 grams of standard neutral soap chips obtained from AATCC Research, Triangle Park, N.C. 27709, and 38 grams of technical sodium meta silicate, Will Scientific Co., Cambridge, Mass., and dried for 30 minutes in a commercial coin operated dryer.
(5) Fed. Test Method Std. 191, Method 5104 - three specimens warp direction only. Test performed on fabric after washing and dry cleaning.

Notes continued on next page.

(6) The shrinkage test used consisted of exposure of fabric to 1300° F temperature for 1 minute (see Appendix A). This thermal exposure greatly exceeds the thermal input anticipated in personnel-survivable fires. This test was used as a research tool to screen candidate stabilization treatments and the shrinkage results obtained greatly exceed the shrinkages obtained in end-item application tests such as the open-pit flame test.
(7) Approx. 20 yds^2 received from AFML on 21 August 1970.
(8) 3 yds^2 received from AFML on 11 January 1971.
(9) LOI (limiting oxygen index) is the minimum percent oxygen by volume in a mixture of oxygen and nitrogen in which the sample will burn.

63E	← same as 63C plus treatment in 10% H_3PO_4 and drying →									Fabric somewhat stiffer	-	18	33	19
63F	same as 63E except rinsed in 15% NH_4OH and dried →									than before treatment	-	18	34	20
64	73-1	10g I_2 in 400 cc 85% H_3PO_4	300	30	15% NH_4OH and rinse		428	10		Treated fabric lighter than original	-	-	39	-

NOTES:

(1) See Table I for fabric description. All fabric was laundered as specified in Table I before treatement.

(2) LOI (limiting oxygen index) is the minimum percent oxygen by volume in a mixture of oxygen and nitrogen in which the sample will burn.

(3) See Appendix A for procedure.

(4) 90% 2.5 dimethyl 2.5 di (t butylperoxy) hexane Lucidol Div.- Wallace and Tiernan

(5) Alcohol solution of proprietary silane-Union Carbide Co.

(6) gamma aminopropyl triethoxy silane - Union Carbide Co.

71-2	None					700	240		Fabric brown - will not dye	-	-	36
71-3	None					610	1400		Fabric brown - will not dye	6	-	28
72-1	30 gm/L $K_2Cr_2O_7$ plus 20 ml/L 98% H_2SO_4	RT	350					Washed once	Fabric very dark		-	23

For notes see end of table.

TABLE VI-4

STUDY OF TREATMENTS FOR REDUCTION OF THERMAL SHRINKAGE OF POLYBENZIMIDAZOLE FABRIC[1]

NOTES:

(1) See Table I in the second status report on this project dated July 16, 1970 for a description of fabric 6-2 used in these tests.

(2) The washing procedure used was to boil the fabric for 15 minutes in 800 ml of soap solution containing 1 gram of neutral chip soap and 1 gram of sodium metasilicate.

(3) See Appendix A for shrinkage test procedure. The % shrinkage is based on the area of the treated sample.

24(2)						5.9				22.2			28.9	11.5	9.4			38.4		These samples were dipped in 0.1 NHCl after washing in NH_4OH rinsed again and pH tested again and then dried at 150° C as before.
25						9.2				27.1			27.1	11.5	9.3			36.0		pH of solution 2.2, of fabric 4.2.
26						16.0				22.9			22.9	11.4	9.5			43.7		
27			5	150 plus 200		10				12.2			-	11.5	9.4			22.2		After a 2nd rinsing in NH_4OH and redrying the thermal shrinkage was 23%.

NOTES:

(1) Cloth sample 73 (see Table I) used for all runs. Except for samples 1, 2, and 3, before drying the samples after treatment in H_3PO_4 they were sandwiched between two 4" square pieces of 40 mesh stainless steel screen and covered by a 6" square of .032" thick copper plate and placed on the aluminum oven shelf with a 2070 gm lead weight on top. For #13 and after the screen and plate were kept in the oven at all times. Before that they were removed with the sample and were allowed to cool. For #13 a 6" square aluminum plate .032" thick was substituted for the copper plate and for #14 and after, the screens were sandwiched between two 8" square aluminum plates .032" thick. Except for the % heat shrinkage all % shrinkage values are based on the original sample area.

(2) The cloth for these runs was dried for 10 mins. at 150°C before treating.

(3) See Appendix A for test procedure. The % thermal shrinkage is based on the area of the treated sample.

TABLE X-3

STUDY OF CHLOROSULFONIC ACID $POCl_3$ TREATMENT (1)

NOTES:

(1) The samples of cloth 78-1 (see Table I) were heated in the oven after H_3PO_4 treatment sandwiched between sheets of 40 mesh stainless steel screen and 6" x 6" x 1/32" aluminum plates under a 2070 gram lead weight. The sheets and weights were in the oven at all times. % shrinkages, except for the heat shrink test, are based on the original area of the fabric.

(2) Samples in brackets were all treated in the same batch of $C\ell HSO_3$. $POC\ell_3$ solution.

(3) See Appendix A for test procedure. The % shrinkage is based on the area of the treated sample.

(4) Same solution as that used for samples 35 to 42.

(5) pH of rinse solution. This is lower than normal. See Table VII.

NOTES.

(1) Cloth 73-1 (see Table I) used after drying 5 minutes at 220°C before treatment. Temperature in drying oven questionable for runs 1 to 9 and ± 5°C thereafter.

(2) LOI (limiting oxygen index) is minimum percent oxygen by volume in a nitrogen oxygen mixture in which the sample will burn.

(3) See Appendix A for procedure. Percent shrinkage is based on the area of the treated material.

It was noted that when preforming the flame shrinkage test on the 2 X 2 squares that a lesser amount of visible fumes were emitted from the fabric when the shrinkage was low, i.e. the more the fabric shrinkage the greater the fumes emitted.

NOTES:

(1) Two pieces of cloth 118-1 described in Table I, one 2 yards long and one 5 yards long, were sewn together and treated in the full scale apparatus shown in Section 3.2. The fabric drying section had 3 banks of 250 watt infrared lamps, 5 lamps per bank, setting of 2500 watt radiant heater 5 (with this setting one end of the heater was hotter than the other), solution 5% chlorosulfonic acid in $POCl_3$ at room temperature, residence time 40 seconds per 2" length, solution feed rate 33 cc/min. The leader section broke at the beginning of the run, therefore, the first 3 feet of fabric was pulled through the reactor by hand. The temperature of the heating solution increased during the run to about 80° C. After treatment, the cloth was heated for 1 1/4 hours at 300°C. The oven temperature dropped to 285°C when the fabric was introduced.

(2) The sample locations were as follows:
1 - initial 3-foot section pulled through by hand
2 - end of first 2-yard section

TABLE XII (Continued)

NOTES: (Cont.)

3 - beginning of second 5-yard section taken from side where radiant heater was at a lower temperature
4 - same as 3 except taken from the opposite side of the section where the radiant heater was the hottest
5 - end of 5-yard section at the same side as 4

(3) Fed. Test Method Std. 191 Method 5104, three specimens warp direction only.

(4) Based on original area.

(5) Dry weight determined as in Fed. Test Method Std. 191, Method 2600 and moisture regain determined by periodic weighings until sample reaches a constant weight when exposed in a constant temperature room at 73 $\pm$ 2° F and 50 $\pm$ 5% relative humidity. Figures 3 and 4 show the plots of 5 moisture regain and the fluctuations in relative humidity during the period the samples were exposed. The relative humidity was measured each morning.

(6) See Appendix A for procedure. % shrinkage is based on the area of the treated sample.

(7) LOI (limiting oxygen index) is the minimum percent oxygen in a mixture of oxygen and nitrogen in which the sample will burn.

(8) Same as note (5) except after drying cloth was conditioned for 20 hours in a dessicator at 78.5° F over a solution of sulfuric acid having a density of 1.27.

Section 4
DISCUSSION OF RESULTS

4.1 Phosphorylation

Initial work was conducted with phosphorus oxychloride (Table XIII). This reagent gave non-uniform treatments resulting in thermal shrinkages generally greater than 40%. Moisture present on the fabric appeared to enhance weight gain and aid in the stabilization of the material. Since water decomposes $POCl_3$ to phosphoric and hydrochloric acids, these acids were examined individually and in combination with $POCl_3$. Treatments of the fabric with hydrochloric acid were ineffective in reducing thermal shrinkage; but treatments with phosphoric acid were successful. A summary of the effects of various combinations of $POCl_3$ and phosphoric acid has been selected from Table II and given in Table XI.

Of all these treatments, direct reaction with 85% phosphoric acid at 210° - 300° F appeared to provide a treated fabric with the best resistance to thermal shrinkage. In addition, an increase in the oxidation resistance of the fabric was noted - an untreated sample had a Limiting Oxygen Index of 0.36 while the treated sample had one of 0.47. However, significant fabric shrinkage occurred during the treatment process itself. For example, a sample treated 30 minutes in 85% H_3PO_4 at 218° F shrank another 23%. While the combined shrinkages of this sample was still lower than the shrinkage of an untreated sample on thermal exposure along (60-65%), the shrinkage on immersion in phosphoric acid was considered too large to be acceptable.

4.2 Candidate Crosslinking Agents

Of all the candidate crosslinking agents evaluated when the study was broadened, chlorosulfonic acid produced the greatest improvement in the dimensional stability of the fabric at the least expense to the desired fabric physical properties. This treatment appears to be completely resistant to laundering or washing in alkaline solutions. Table XIV summarizes the thermal shrinkage results of fabrics treated by the candidate systems.

Table XIII

SUMMARY OF EFFECTIVENESS OF $POCl_3$ - PHOSPHORIC ACID TREATMENTS

	Treatment	Thermal Shrinkage
1a.	$POCl_3$ (vapor) + PBI $\xrightarrow[225 - 245°F]{\text{nitrogen}}$	42
b.	$POCl_3$ (vapor) + PBI $\xrightarrow[235 - 300°F]{\text{oxygen}}$	54
c.	$POCl_3$ (vapor) + PBI $\xrightarrow[225 - 235°F,\ H_3PO_4]{\text{oxygen}}$	48
2a.	$POCl_3$ (reflux) + PBI $\xrightarrow[218 - 228°F]{\text{oxygen}}$	50
b.	$POCl_3$ (reflux) + PBI $\xrightarrow[218 - 228°F,\ H_3PO_4]{\text{oxygen}}$	23
c.	$POCl_3$ (reflux) + PBI $\xrightarrow[218 - 228°F,\ POCl_3\ (liq)]{\text{oxygen}}$	41
	$\xrightarrow[3\ hrs.\ in\ air]{heat\ 700°F}$	28
3.	$POCl_3$ (liquid) + PBI $\xrightarrow[70 - 230°F]{}$	45
4.	$POCl_3$ (liquid) + PBI $\xrightarrow[240°F]{\text{pyridine}}$	49
5.	H_3PO_4 (85%) + PBI $\xrightarrow[210 - 300°F]{}$	23

Table XIV-1

Results of Treatments Utilizing Candidate Reagents (1)

Reagent	Conditions	Thermal Shrinkage**	Comments
10% Potassium Dichromate Sol'n	pH = 1, 212° F 5 min*	42%	Fabric burns in air due to residual dichromate
1% $KMnO_4$ Sol'n	pH ≅ 12, 212° F 1 min*	42%	Fabric turns very dark - burns in air
0.7% Nitric Acid	212° F, 5 min*	56%	Fabric neutralized with NH_4OH prior to oven heating - no fabric color change
0.7% Nitric Acid	212° F, 5 min*	22%	Fabric turned deep purple color in oven
30% Hydrogen Peroxide	400° F, 15 min	64%	
5% Chlorosulfonic Acid in Phosphorus Oxychloride	230° F, 5 min followed by oven treatment at 360° C for 10 min	15%	Sl. darkening of fabric
10% H_2SO_4	400° F, 5 min	45%	Fabric shrinks

Silane A-1100	200° C, 15 min	60%	
37% Formaldehyde Solution	boiled, 5 min 210° C, 10 min	61%	
2.1% Sodium Hypochlorite solution - 0.4% Sodium Hydroxide	boiled, 5 min 210° C, 5 min	37%	

(1) Data selected from Tables III to VII.

*Following immersions in reagent solution, fabric was heated in oven to 390-400° F for about 15 min.

**Determined by exposing 2" x 2" fabric swatch between metal gauze restraints to ~ 1300° F for 1 min. Shrinkage quoted as $\frac{\text{initial area - final area}}{\text{initial area}} \times 100\%$.

Except for nitric acid, the oxidizing agents were largely ineffectual. Of particular note in the case of dichromate and permanganate solutions is the tenacious pick-up of these agents by the fiber. Even after extensive washing with soaps and reducing agents (oxalic acid, stannous chloride - hydrochloric acid, sodium thiosulfate), a substantial percentage of the dichromate and permanganate remained in the fiber. Since benzimidazoles are known to form a wide variety of complexes with metals (Ref. 4), it is conceivable that the chromium and manganese are chelated by PBI. If these metals are in fact chelated, they may be used as mordants to permit the uniform dyeing of the fiber - which is a prime requisite for the development of commercial interest in the fiber.

Treatment of PBI with nitric acid and heat produced a purplish tinge to the fabric. Concomitant with the purpling was a reduction in the thermal shrinkage to 22%. The coloration and thermal stabilization could be prevented by neutralizing the acid treatment with ammonium hydroxide solution before heating the fabric in the oven. It was found that fabric that had been turned purple could not be dyed with the dyes normally used with PBI. On the other hand, fabric, first dyed, could not be turned purple or stabilized through treatment with nitric acid and heat. A hypothesis consistent with these observations is that both the acid and the dye react with the same site on PBI - probably the amido nitrogen.

4.3 Chlorosulfonic Acid Treatment

In the batch chlorosulfonic acid treatment, PBI fabric*, dried at 300° F for ten minutes, is immersed in a solution of 5% by volume chlorosulfonic acid (Eastman) in phosphorus oxychloride (Matheson Coleman and Bell) for 5 minutes. The fabric is removed and padded with absorbent towels to approximately a 50% wet weight addition. The fabric is then placed in a 340° C muffle furnace for 30 minutes. Following the heat treatment, the fabric is neutralized with a 10% ammonium hydroxide solution, rinsed, and dried.

An optimization of the chlorosulfonic acid process was undertaken to determine the reaction conditions that would give maximum dimensional stability to a minimum change in PBI fabric flammability, color, and tensile strength.

*Fabric dry cleaned and then washed with 1% neutral chip soap, 1% sodium silicate solution in commercial laundering equipment.

Table XV which gives data selected from Tables X and XI shows the effect of the temperature of the chlorosulfonic solution on the thermal shrinkage of 2/1 twill fabric.

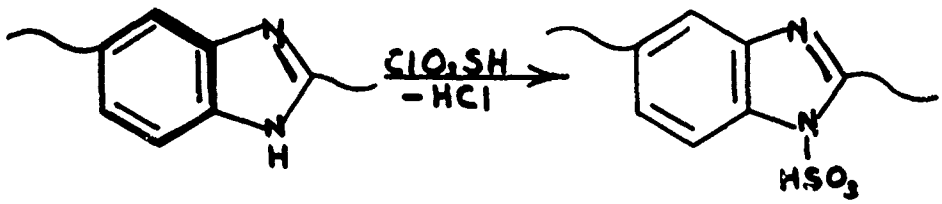
As the solution temperature is increased, so is the permanent weight addition to the fabric. In addition, the oven temperature has a decided effect on the weight gain. Figure 7 shows the correlation between the per cent shrinkage (in the thermal shrinkage test) and the per cent weight gain. Of particular note is the effect of oven temperature. In fact, a trade-off between oven temperature and time was found. For example, identical thermal shrinkage results are obtained for fabric heated at

$400^{\circ}C$ for 2 min
$360^{\circ}C$ for 10 min
$340^{\circ}C$ for 25 min

This implies that the reaction rate increases 1.5 times for every $10^{\circ}C$ increase in temperature.

The graphic presentation of Figure 8 shows how different conditions of time and temperature of treatment may be selected to obtain equivalent levels of stabilization of PBI through treatment with chlorosulfonic acid. Of course, stabilization is not the only result of exposure to the treatment. Other changes resulting in darkening and reduction in physical strength occur at the same time. Indeed, changes of this kind may occur as a result of treatments which do not yield optimum stabilization. This combination of behavior may be represented as shown in Figure 9, where the influence of time and temperature on the coexisting properties of stabilization and physical attributes are shown. Over-all optimization of treatment requires selection of a desired field within such a chart.

A theory of reaction consistent with the above information is that two reactions occur. The first takes place on immersion of the fabric in the chlorosulfonic acid solution.



If the fabric at this stage is neutralized with 10% NH_4OH solution, the fabric shows no weight gain.

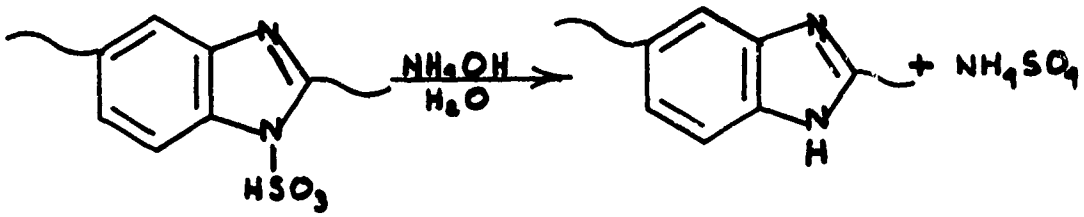


Table XV

Effect of Temperature of 5% Chlorosulfonic Acid in Phosphorus Oxychloride on Fabric Thermal Shrinkage

Run No.	Solution Temperature °C	Time of Immersion (Min.)	Oven Temp/Time °C (Mins.)		Percent Weight Gain %	Thermal Shrinkage (1) %
10	room temp.	5	320	20	2.04	57

NOTES:

(1) See Appendix A for Test Procedure.

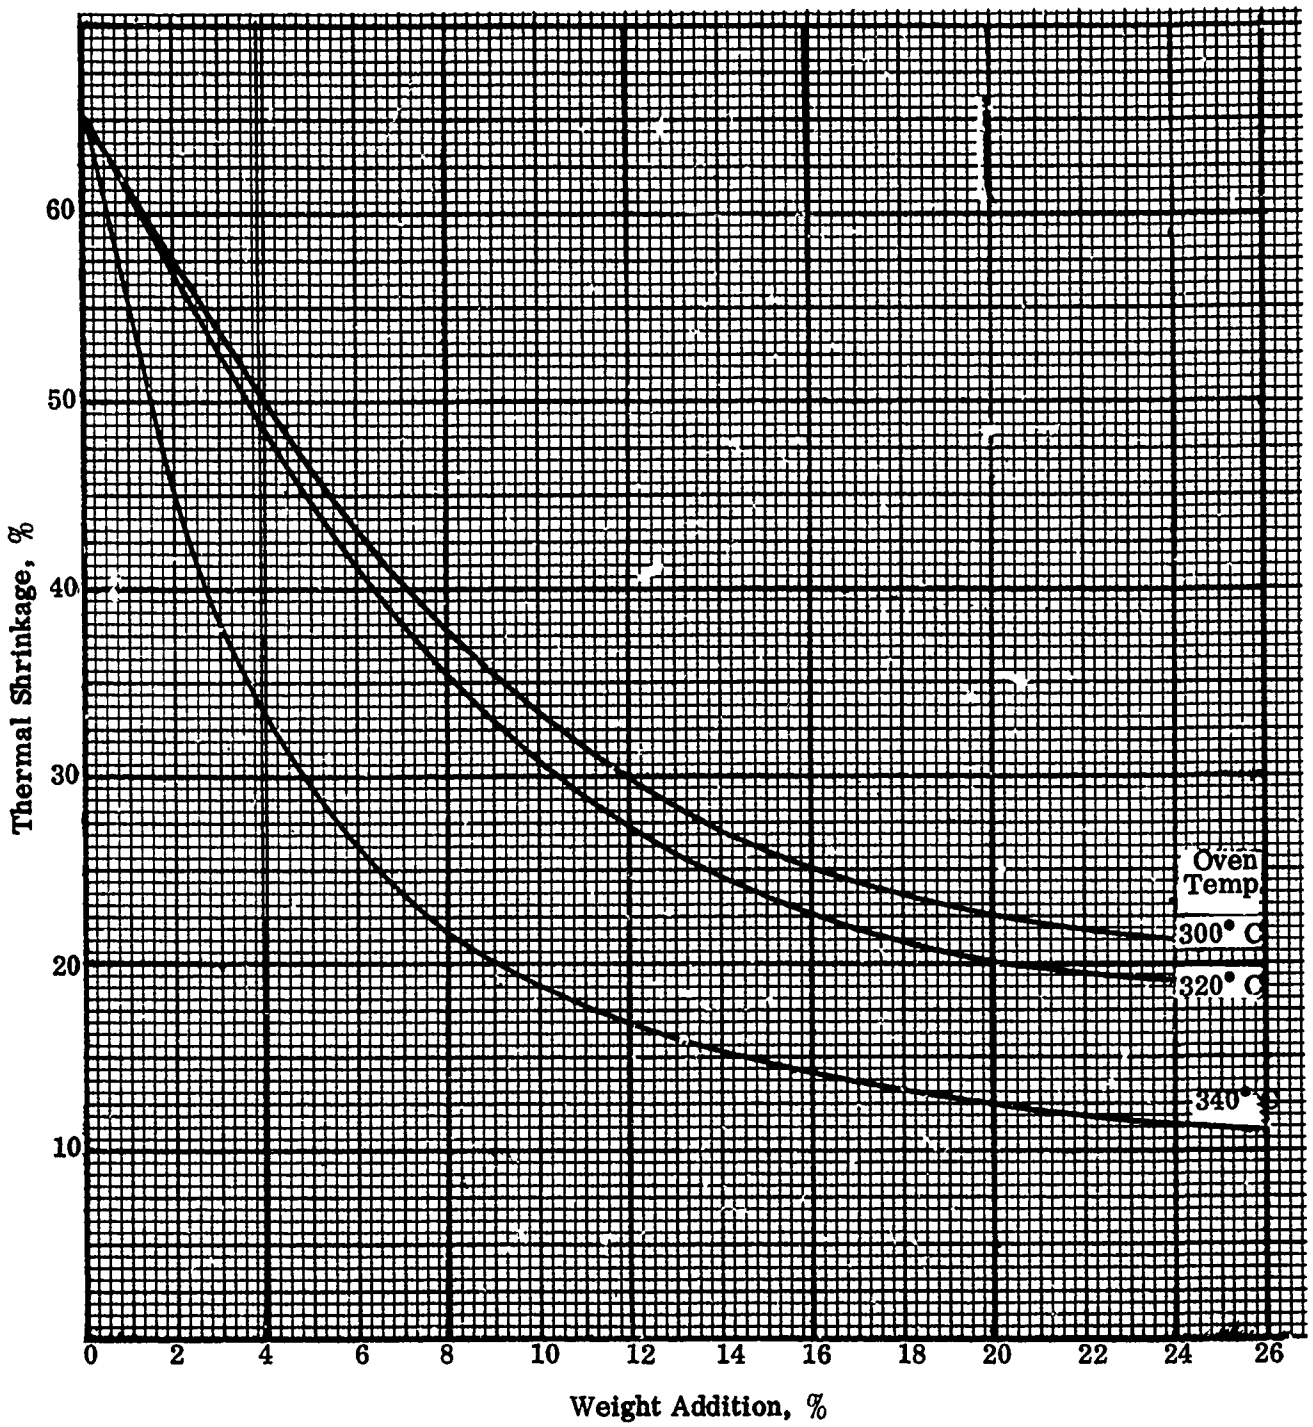

FIGURE 7

Fabric Thermal Shrinkage Versus Weight Addition

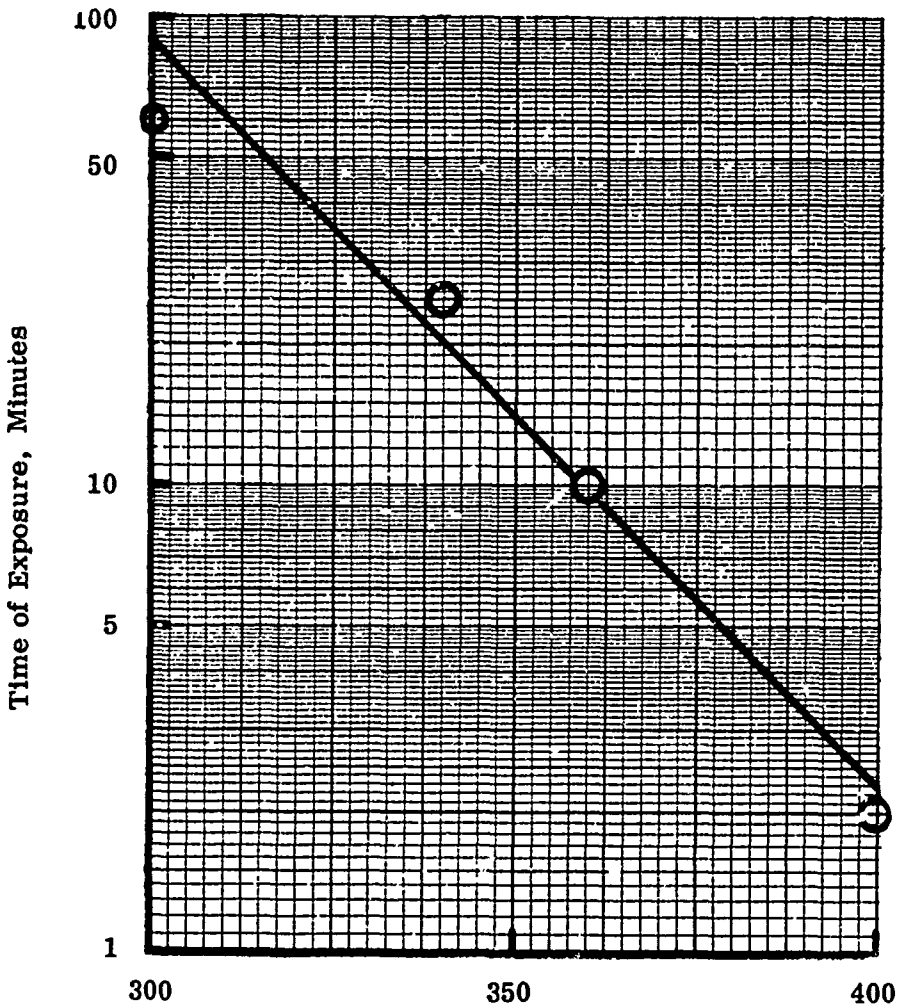

Figure 8

Conditions of Time and Temperature of Treatment Producing Equivalent Stabilization of PBI with Chlorosulfonic Acid

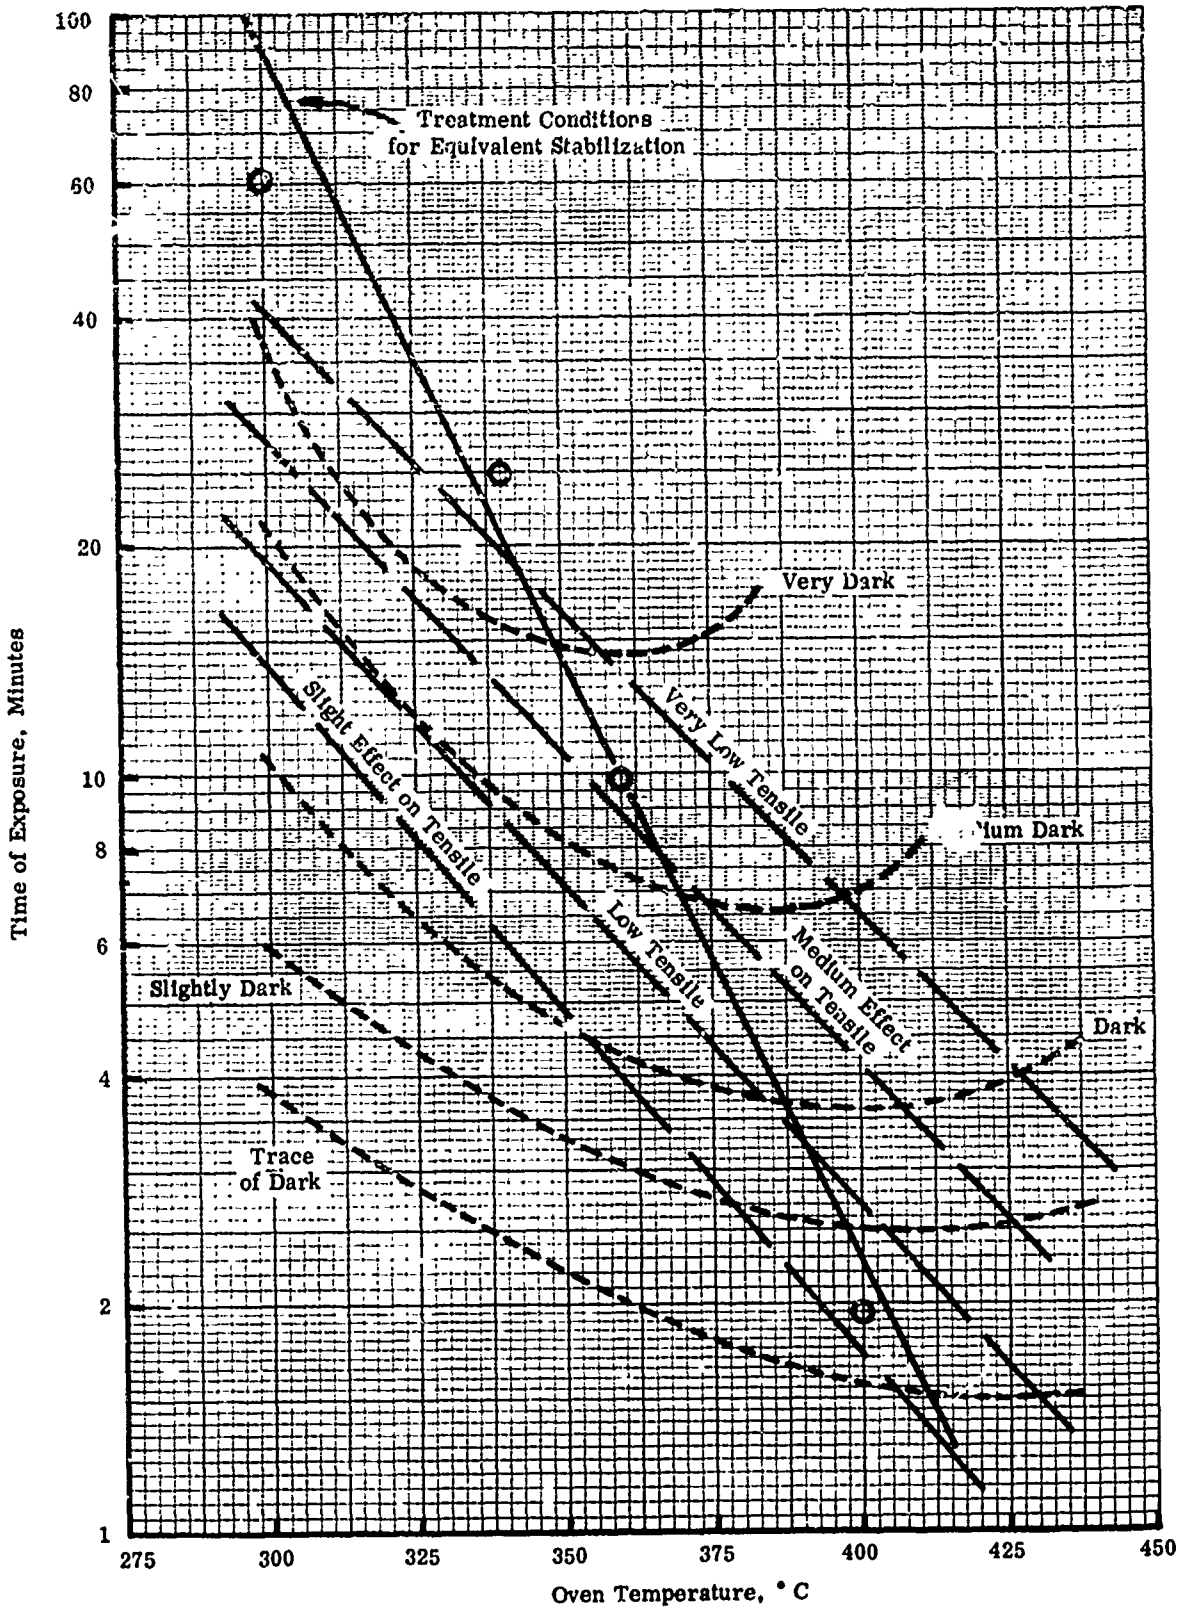

Figure 9

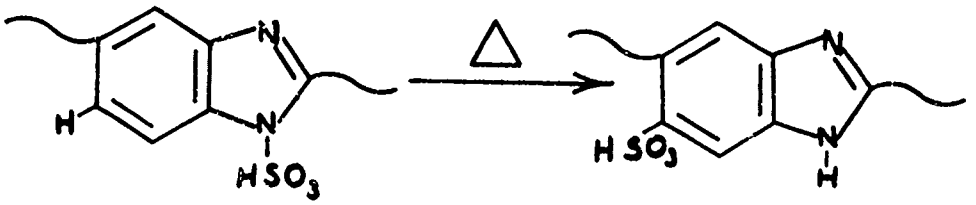
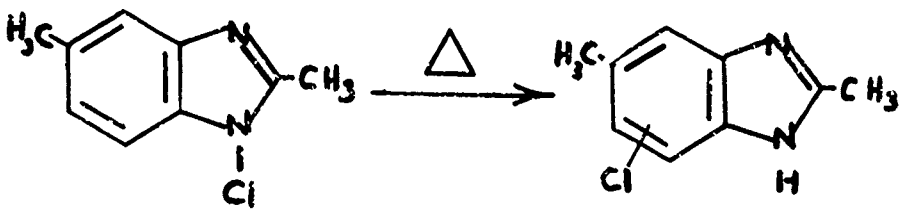
Representation of Effects on Physical Properties in Stabilization Treatment of PBI

If, however, the material is heated, the following rearrangement may occur:

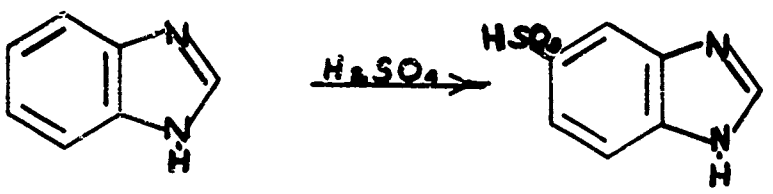


A sulfonate group on the ring is not susceptible to hydrolysis with ammonium hydroxide – thus, a permanent weight gain, durable to laundering, is obtained after the heat treatment.

Lending credence to the proposed theory is the fact that nitrogen-substituted benzimidazoles are known to rearrange under the influence of heat (Ref. 5). For example,



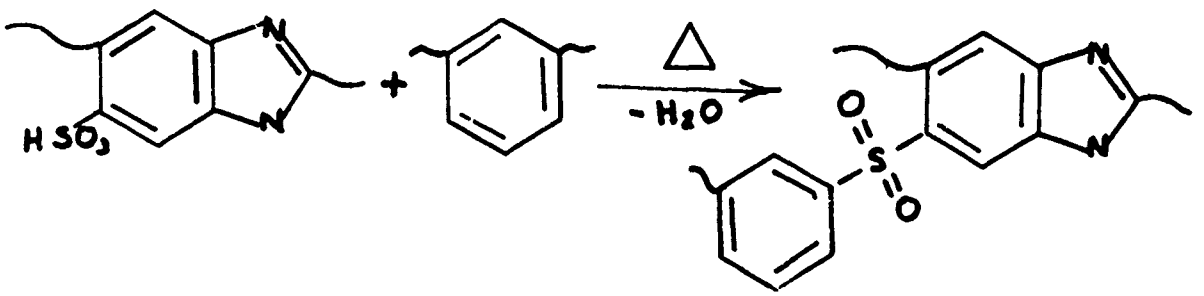
Also well documented is the sulfonation of benzimidazoles with sulfuric acid and chlorosulfonic acid (Ref. 6).



In the patent literature these sulfonations generally involve dissolving the benzimidazoles in the sulfonating reagents. Since both sulfuric and chlorosulfonic acids are excellent solvents for the polymer, direct treatment with these reagents causes the fabric to be reduced to a jellied mass. To minimize the dissolution, solutions of

chlorosulfonic acid in various non-solvents for the fabric were evaluated. Phosphorus oxychloride proved to be the best because it was non-protonating, completely miscible with chlorcsulfonic acid, and effective in rapidly penetrating the PBI.

The cross-linking of the fabric appears to occur simultaneously with the rearrangement of the sulfonate group. Cross-linking through sulfonate groups probably occurs as shown below.



4.4 Seven Yards of Fabric Treated for Evaluation by Technical Monitor

As shown by the test results in Table XII, the seven yards of fabric treated by the chlorosulfonic acid in $POCl_3$ meets all the goals for Phase I. It has tensile and elongation properties equal or better than the control, essentially the same flammability, and the treatment shrank the fabric only 14%. The color of the fabric was affected only very slightly, the fabric is still dyeable and the hand and moisture regain properties are excellent. The fabric has 27% thermal shrinkage by our very severe thermal shrinkage test, however, our test produced about three times higher shrinkages than the open pit flame test. Consequently, shrinkages of the order of 8-10% are anticipated in the pit test. In fact, another lot of PBI fabric treated in this way under contract F33615-71-C-0342 and fabricated into flight suits performed outstandingly in pit test exposures at Maynard, Mass., August, 1971.

As shown in Tables X and XI it is possible, using this chlorosulfonic acid treatment, to produce fabric having much better resistance to thermal shrinkage than 27%, but problems are encountered with fabric darkening and stiffening. It is probable, however, that with commercial equipment and careful choice of reaction conditions it will be possible to produce light colored fabric with a good hand having less than 20% thermal shrinkage even by our test.

4.5 Tow Treatment Facility

The tow processing line was constructed using the fabric treatment facility as a model; however, provisions were made on the tow line so than precise control could be maintained of processing times, temperatures, and the gas environment to which the tow was exposed.

Initial trial runs on the equipment demonstrated the effectiveness and uniformity of the treatment. Twisted PBI tow, 30 plies of 550 fil fiber with about 1 1/2 twists per inch, was run through the continuous process at three speeds, 1.18 in/sec, 1.27 in/sec, and 1.88 in/sec. An oven temperature of 475° C and a nitrogen gas purge was employed. Thermal shrinkage results were obtained on tow sections by placing individual fibers in glass tubes, and then heating the tubes until the fiber became a blackened char (about 400° C for 1 hour).

Table XVI summarizes the thermal shrinkage results, obtained at two processing speeds, of fibers selected from the cross-section of the tow.

Table XVI. Thermal Shrinkage of 30 Ply Tow

Processing Speed	Residence Time in Oven	Oven Temp.	Fiber No.	Thermal Shrinkage
1.18 in/sec	35.7 sec	475° C	1	22.1%
			2	23%
			3	23%
			4	22.6%
			5	22.9%
			6	23.4%
			7	24.8%
			8	30.6%
			9	25.3%
			10	19.8%
			11	19.7%
			12	19.7%
			13	17%

Table XVI. Thermal Shrinkage of 30 Ply Tow (continued)

Processing Speed	Residence Time in Oven	Oven Temp.	Fiber No.	Thermal Shrinkage
			Average	21.8%
			Control A	62.2%
			Control B	58.3%
1.88 in/sec	22.3 sec	475° C	1	28.6%
			2	27.7%
			3	23.5%
			4	23.6%
			Average	25.9%
			Control A	52%
			Control B	54.5%

The treated fiber produced in these first trials had a chocolate brown appearance: to minimize fiber discoloration, the oven temperature was lowered. Various temperature settings and oven residence times were evaluated to produce low thermal shrinkage fiber with minimum discoloration. During these trials it was found that a nitrogen purge did not appreciably prevent discoloration, and the purge was eliminated as a processing step. The process condition that were finally established are given in Table. XVII.

Table XVII

Final Processing Conditions Established for Tow Line

Fiber:	16,500 filament tow; twisted ~1.5 $\frac{\text{twists}}{\text{inch}}$
Line Speed:	10 ft/min
Chlorosulfonic Acid Make-up:	5% ClO_3SH (Eastman): 95% $POCl_3$ (Ventron)
Residence Time in Acid Saturator:	~2 sec.
Tube Furnace Temperature:	430° C
Nitrogen Purge in Furnace:	No
Residence Time in Furnace:	21 sec.
Ammonium Hydroxide Concentration:	~58% NH_4OH
Residence Time in Ammonium Hydroxide:	~9 sec.
Drying Oven Temperature:*	room temp.

*The final dry step was accomplished by placing the fiber (on a bobbin) in a 300° F oven for 12 hours.

Fibers selected from the cross-section of the treated tow showed the thermal shrinkages and tensile strengths listed in Table XVIII.

Table XVIII

Thermal Shrinkage of Individual Fibers

Control	60.2%
Fiber A	18.6
Fiber B	23.3
Fiber C	21.4
Fiber D	22.0
Average for treated fibers	21.3%

Tensile Strength*

Control 1	52*
Control 2	51
Control 3	59
Fiber D	54
Fiber E	51
Fiber F	51

*arbitrary units

The average shrinkage of 21.3%, the light color, and the maintenance of the tensile strength of the fiber indicated that the process had been developed to the point where a large scale production run could be made with confidence.

One and one-half pounds of tow were processed under these conditions and submitted to the Air Force Materials Laboratory for approval. Approval of the tow and to proceed with the processing of 30 lbs of PBI was received on July 16, 1971.

4.6 Production of Treated Tow

Five-thousand filament tow (1.5 denier/filament) was plied to 15000 filament tow having approximately 1-1/2 turns per inch. This tow was unreeled from 3 inch diameter bobbins into the continuous processing line. The saturator was filled with 5% by weight chlorosulfonic acid in phosphorus oxychloride. At the selected line speed the tow remained immersed in the 6 inch saturator for 3 seconds. The furnace following the saturator was set at 430° C. The period of immersion in the ten-inch neutralization tank was about 5 seconds. The tow was arranged to make seven double passes through the water rinse tank, giving a residence time of about 2 minutes. The drying oven was set at 420° C. The initial bobbin was processed with the above arrangement, and second bobbin was processed similarly, with the exception that the drying oven temperature was raised to 460° C.

The color of the fiber produced on the first and second bobbins was quite light, and it was concluded that a somewhat higher oven temperature could be tolerated. The oven temperature accordingly was raised to 448° C, and 4 additional bobbins were produced with this single change in processing conditions. The first two bobbins were designated Lot 1 and the last four bobbins were designated Lot 2.

4.7 Conversion of Tow into Fabric

The PBI tow, processed as described in 4.6, was supplied as two lots wound on six bobbins to Celanese Research Company to be crimped and cut to 2-inch length. The material could be handled satisfactorily in the crimping and cutting operations, but it was observed that the fiber affected the metal parts of the processing equipment. Following the processing it was found that aluminum parts were pitted and steel parts were heavily rusted. This action suggests that some of the fiber contained a residue of alkali while another part remained acid through incomplete neutralization. Support of this explanation is furnished by the observations of those handling the fiber at Celanese that the smaller lot, which had been processed at 430° C had a slight odor of ammonia. The larger lot, which had been processed at 448° C was characterized as smelling of "nitrates", i.e., gave an impression of acidity. It is evident that the

neutralization and water-washing steps in the continuous processing facility varied in effectiveness. During the processing, pH measurements of the damp tow leaving the rinse tank were made with indicator paper, but indications of neutrality obtained in this way obviously were not totally adequate.

The crimped and cut tow was sent to Textile Research Services, Inc., Raleigh, North Carolina, for weaving into cloth. In preparation for carding the fiber was sprayed with Nopco 2152P antistat. Upon attempting to card and draw the fiber it was found that the card loaded up with fiber after a very short time, preventing continuation. A relatively hard, powdery substance was found to build up on metal parts as it was attempted to process the fiber. This behavior is believed to be a further consequence of the presence of residual alkali or acid on the fiber as noted at Celanese Research Company. It is probable that the antistat material reacted with the acid and alkali to produce a coating on the fibers having adhesive qualities. This adhesiveness probably caused the card loading, and the material observed to build up on metal parts may well have been the reaction product of the antistat.

In order to overcome the behavior just noted the fiber was scoured. The scouring procedure was carried out with Igepon P in water at 190° F. The scouring cycle consisted of 15 minutes washing, two rinses of twenty minute duration, and 5 minutes extraction. After drying and conditioning Nopco 2152P antistat was again sprayed on the fabric. Following this treatment the fiber processed normally. The procedures followed in converting the fiber to cloth at Textile Research Services, Inc., are summarized in Table XIX.

Table XIX

Spinning and Weaving Procedure Applied to Crimped and Cut Tow

Step	Lot 1	Lot 2
1. Card, draw, and rove to spin and ply	Yarn no. 37/2 Twist 3.85 T.M. 'Z' x 14.5 T.P.I. 'S'	Yarn no. 37/2 Twist 3.85 T.M. 'Z' x 14.5 T.P.I. 'S'
2. Number spool	140 spools 380 yards/spool	140 spools 700 yards/spool
3. Make 2 warps via the silk system	140 ends/band 20 bands 3 turns/band	140 ends/band 20 bands 6 turns/band
4. Draw and reed	8 body harness (skip draw) 4 selvage harness 80 total selvage ends (40/side) 26.5/2 Reed 52" Reed width	Same
5. Weave	2 x 2 L.H. Twill 54 x 52 Off Loom Const. 4.4 oz/yd^2 Fitting same as warps	Same

4.8 Performance of Fabric

The fabric produced from the tow processed as described in 4.6 had excellent color and hand, appearing entirely like other samples of fabric examined previously. Measurements were made of the tensile strength, limiting oxygen index and thermal shrinkage of samples taken from the two lots of cloth. These data are presented in Table XX. It will be seen that the two lots differed importantly in their response to thermal exposure.

Table XX

Evaluation of Fabric Woven from Treated Tow

Property	Lot 1	Lot 2	Control
Tensile Strength, lb/inch width	74	73	94-96
LOI	0.40	0.50	0.41
Shrinkage, %	57	32	61

Lot 1 differed very little from an untreated control, whereas Lot 2 showed much improved shrinkage and a significant increase in oxygen index. The shrinkage obtained with Lot 2 was like that obtained earlier in treating already formed fabric. The oxygen index of the Lot 2 fabric prepared from tow was found to be higher than that of fabric treated as such.

Since the essential difference in preparing lots 1 and 2 was the oven temperature, no other reason for the differences in behavior can be advanced. The discussion of PBI behavior has made it clear that the thermal exposure following chemical treatment is important in determining response, but the levels selected in tow processing were within the range found useful. The temperature level of 430 selected initially and utilized in processing Lot 1 was selected on the basis of preliminary work (using single fibers for evaluation) as the lowest effective temperature and therefore a level at which fiber discoloration would be least. Upon observing that the fiber produced as Lot 1 was very little affected in color the decision was made to raise oven temperature 18° C, as reported. The color of the fiber so processed was not affected importantly and it is evident that this change in oven temperature was of profound importance.

It is apparent that the conditions of treatment chosen in processing the tow were too conservative. Referring to Figure 9, it may be appreciated that other conditions, specifically those involving higher oven temperatures, at the fixed residence time chosen, would have given consistently adequate stabilization at the cost of some additional darkening of the fiber. The limited experience in working with tow contributed to the conservative choice of conditions; in subsequent treatment of tow it will be possible to raise the level of stabilization substantially. Further work on tow processing and preparation of fabric from treated tow is recommended in order to achieve the desired level of stabilization in conjunction with acceptable fabric properties.

Section 5

CONCLUSIONS

The shrinkage which occurs when polybenzimidazole (PBI) fabrics are exposed to the high temperatures encountered in flames can be reduced substantially through suitable chemical treatment of the fibers or of finished cloth. A treatment involving immersion in a solution of 5% by weight chlorosulfonic acid in phosphorus oxychloride followed by thermal treatment at 300°- 450° C was found to reduce the area shrinkage of treated fabric by 50% without affecting the hand and drape, color, or physical properties of the fabric to an important degree. The flammability of the treated fabric is essentially unaffected. The treatment is durable, permitting the fabric to be laundered normally.

The process for thermally stabilizing PBI is suited to continuous processing of fiber in the form of tow or fabric. A lot of PBI fabric, treated as described, and fabricated into flying suits performed exceptionally well on exposure in flame pit tests, indicating that the treatment provides additional properties of high value to PBI fabric. PBI tow was processed on a continuous basis with the treatment, the tow being subsequently woven into cloth. The thermal stabilization process developed has been shown to provide the necessary fabric improvement while enabling fabric color and physical properties to be acceptably maintained.

The success achieved in developing a practical stabilization process for PBI supports the recommendation that the parameters involved in satisfactory treatment of PBI tow be subjected to additional investigation. Such further work on tow treatment will enable full-range utilization of this important improvement in manufacturing PBI fabric for all Air Force applications.

Appendix A

TEST FOR FABRIC SHRINKAGE DURING FLAME IMPINGEMENT

Equipment

Meker Burner-Cenco Cat #11043
Two 2 1/4" square pieces of 40 mesh stainless steel screen
300 gram weight-made by melting a 60/30 mixture of lead and 50/50 solder in a 600 ml stainless steel Beaker, Fisher Cat #2-583
4 x 4 Corning Ware Ceramic Dish (P-41 Petite Pan)
2 x 2 Steel die which cuts a sample 4.0 in^2 in area

Procedure

1. Mount the ceramic dish on a ring stand so that it is 3/8" above the Meker burner and adjust gas to give a temperature of 800° F ± 10° F as measured by a copper constantan thermocouple touching the center of the ceramic dish.
2. Warm the weight to 450° F ± 10° F (about the melting point of the lead solder mixture).
3. Place a 2" x 2" cloth sample (A_o = 4.0 in^2) die cut from the sample to be tested between the pieces of wire screen and lay it in the hot ceramic dish and cover with the weight. Remove after 1 min. ± 5 secs.
4. After the cloth is cool, measure area A_1 by tracing an outline on a piece of 10 x 10 per 1/2" rectangular coordinate graph paper and counting the number of squares. Calculate % shrinkage.

$$\% \text{ shrinkage} = \frac{A_o - A_1 \times 100}{A_o}$$

5. Repeat above and report the average shrinkage of the two samples.
6. The data below obtained on untreated fabric shows the precision to be expected from the test.

Fabric	Original Area	Area After Heating	% Change (based on original area)
Continuous Filament	4 in^2	1.50 in^2	-62.5%
Continuous Filament	4 in^2	1.44	-64.0%
2.85 oz/yd^2	4 in^2	1.56	-61.0%
6.17 oz/yd^2	4 in^2	1.62	-59.5%

Appendix B

FIBER TENSILE TEST METHOD

Equipment

Tensile Testing Machine suited for measurements of 0-15 lb at 12 inches/minute.

Sample jaws suited to clamp one end of a loop formed from 6-7 inch fiber and suspend other end of loop.

Procedure

1. Form a loop of a length of fiber. holding the free ends between thumb and forefinger.
2. Clamp end of fiber loop formed at free ends in tester jaw.
3. Hook blind end of loop over suspending rod on other jaw of tester.
4. Check that loop is secure with jaw separation 2-3/4" - 3-1/4".
5. Set tester speed at 12 inches/minute.
6. Record tensile at break.
7. Repeat, determining results for 5 fibers.
8. Calculate and report the average tensile at break for the 5 samples tested.

Appendix C

PROCEDURE FOR DETERMINING SHRINKAGE OF POLYBENZIMIDAZOLE FIBER

Standard Testing Procedure, Number 25 - Dec. 1970

Equipment

3 glass tubes, 1 ft. long, 1.2 mm ID. Circulating Air Oven at 500° C.

Procedure

1. Thread fiber through the glass tube using slight suction, cut the fiber at both ends of the tube; measure its length to the nearest 1/32".
2. Repeat step 1 with two more fibers in two more tubes.
3. Place the tubes in an oven set at 500° C ± 5° C as measured with a calibrated or thermocouple for 10 mins.
4. Remove the tube from the oven and remeasure fiber lengths to the nearest 1/32".
5. Determine linear shrinkage based on 1' initial length and length as measured in tube after shrinkage.
