ACKKNOWLEDGEMENTS

We are grateful to Mr. Kyle Cook of Environmental Security at Marine Corps Base Camp Pendleton for his support of this applied research project and the wide-ranging technical work required to understand water quality in the lagoon. We thank the Santa Margarita River Nutrient Initiative Stakeholder Group and members of the technical review team for their support and feedback throughout the study.

EXECUTIVE SUMMARY

This report describes current water quality conditions in the Santa Margarita Estuary monitored over a 21-month period between September 2014 and June 2016. The data collection was designed to assess current water quality conditions as they relate to eutrophication, as well as to compare to historical monitoring datasets collected over the past 10 years. The data were collected by the Navy's Environmental Sciences Branch of the Space and Naval Warfare Systems Center Pacific for Environmental Security, Marine Corps Base Camp Pendleton. This report describes the background, technical approach, methods, and results of collected data with a summary and analysis of water quality and the dynamics and main physiochemical processes that control it.

The Santa Margarita Estuary sits entirely within the boundaries of Marine Corps Base Camp Pendleton. It forms up where the Santa Margarita River meets the Pacific Ocean just north of Oceanside, California. The estuary was listed as impaired for eutrophication by the San Diego Regional Water Quality Control Board in 1986. A stakeholder group was formed to investigate the level of impairment in 2008 and to conduct water quality modeling. This group is currently working with the San Diego Regional Water Quality Control Board to formulate numeric objectives under a nutrient numeric endpoint framework that will encompass both ecological response metrics of macroalgae biomass as well as dissolved oxygen to support beneficial uses. These metrics will form the basis for future regulation of the estuary under an alternative Total Maximum Daily Load (TMDL). The monitoring survey reported here is an update to the 2008 water quality dataset.

The technical approach was designed to collect key water quality parameters at the spatial and temporal scales required to capture the dynamic nature of the estuary both hydrographically as well as its biochemical response to nutrients in the form of algal production and dissolved oxygen. The current monitoring expanded on historic datasets and included: a 21-month continuous record of 15-min salinity, temperature, dissolved oxygen, and pH monitored at two locations and water level at three locations; monthly collection and measurements of discrete water samples at six locations for a suite of nutrients, phytoplankton chlorophyll-*a* (Chl-*a*), and suspended solids; monthly collection and measurements of macroalgal biomass, cover, speciation and carbon, nitrogen, phosphorous content; benthic algal Chl-*a*; a qualitative assessment of submerged aquatic vegetation and cover at six locations; two spatial mapping surveys; monthly mouth berm elevation measurements; and a bathymetry survey. The key results of the monitoring are summarized in Section 4 of the report.

This study, together with previous field studies, have consistently shown the Santa Margarita estuary to be a highly dynamic water body with water quality conditions that are tied primarily to seasonal changes in rainfall, freshwater discharge, summertime heating, and changes in tidal exchange with the ocean as a result of natural berm building at the mouth. These same factors result in spatial variations that occur primarily along the longitudinal axis of the estuary, which shows a predominantly oceanic regime west of the Interstate Highway 5 (I-5) Bridge, a freshwater regime east of the Stuart Mesa Bridge, and a transitional area between them. The magnitude and extent of these processes directly impact the level of nutrient loading and resultant algal growth and dissolved oxygen levels.

Conditions measured in this recent monitoring were significantly impacted by a 9-month duration of a completely closed-mouth, limited freshwater flow, and by relatively limited exchange when the mouth was open. The outcome was one in which the estuary became warmer, saltier, and accumulated nutrients through summer and responded with an increase in macroalgae, benthic algae and phytoplankton and a general reduction in dissolved oxygen levels. The slow build up of

nutrients, observable mainly because the mouth was closed, was consistent with their release during sediment diagenesis and augmented with storm water runoff and inflow of watershed groundwater.

The impact of increased macroalgal biomass in the estuary during the closed-mouth condition in summer showed a general decrease in daily average dissolved oxygen values as well as large daily swings. Overall, 21.1% of dissolved oxygen levels were below 5 mg/L, the current Basin Plan objective, though the percentage changed substantially between open (9.3%) and closed (28.2%) conditions. About 7% of the data continuously fell below 5 mg/L for an entire day. The overall oxygen levels were comparable to historic datasets and comparable to the median condition found in California reference estuaries.

The two benchmarks under consideration for the alternative TMDL are based on macroalgal biomass and dissolved oxygen concentrations. The relationship between modeled maximum macroalgal biomass and minimum daily dissolved oxygen from the 2008 dataset was used by the Regional Board to derive a proposed threshold macroalgal biomass value of 57 g dw/m^2. The dissolved oxygen threshold was based on meeting California's delisting policy: 5 mg/L in the 10^{th} percentile of a 7-day average of the daily minimum. The relationship between maximum macroalgal biomass and minimum dissolved oxygen evaluated in this dataset ($R^2 = 0.30$, closed-mouth only) resulted in a biomass concentration of 129 g dw/m^2, a value that is a factor of 2.2 times greater than the modeled value based on the 2008 dataset. These results suggest that higher levels of macroalgae may be present and still meet the 5 mg/L dissolved oxygen threshold.

Comparisons of ambient nutrient concentration levels to historic datasets indicate a significant sixfold decrease in total nitrogen since 2006 with a relatively consistent level of total phosphorous. The long-term decrease in nitrogen was attributed to an overall reduced freshwater and nutrient load from the watershed as well as reduced groundwater load entering into the estuary at the I-5 Bridge associated with an historical agricultural field. Though the level of nitrogen has decreased and phosphorous levels have remained about the same, macroalgal biomass increased fourfold since 2008, while cover increased by 30%. The increases in macroalgae over time appear to be related more to variations in physical conditions of the estuary such as freshwater inflow and exchange with the ocean, than to nutrients, an observation that has been made in other California estuaries.

ACRONYMS

BA	Benthic Algae
BOD	Biological Oxygen Demand

Figures

1. Santa Margarita River Watershed. The estuary is at the southwestern end of the watershed within Marine Corps Base Camp Pendleton north of Oceanside, California. Photo supplied by Google Earth.... 3
2. Field work domain for Santa Margarita Estuary monitoring. Four bridges: north and southbound Interstate Highway I-5; North County Transit District Railroad Bridge; and Stuart Mesa Road Bridge cross over the estuary and provide key geographical landmarks for the study.... 3
3. Continuous water quality sensor buoy and water level (LL) station locations. The buoys were ~ 10 m downstream of the bridge pilings. The aerial was collected when the mouth was fully closed in March 2016. A barologger unit (not shown above) was located directly on shore underneath the I-5 Bridge southbound lanes 10
4. Monthly monitoring stations. Six macroalgal biomass and cover and benthic algae intertidal station locations: MA1, MA2, MA3, MA4, MA5, and MA6. Discrete water samples for nutrients, TSS, and Chl-*a* were collected monthly at the Ocean, MA1, MA3, MA6, and the I-5 and Stuart Mesa Bridges 11

5. Nominal axial mapping survey transect between the ocean and the most north-eastern portion of the estuary reachable by kayak from the west. Discrete water samples were collected at 11 station locations along the transect as well as in the ocean. The ocean station was ~ 500m south of the normal monthly sampling location. Axial stations 4 and 7 were collected at the I-5 and Stuart Mesa Bridge buoys, respectively 12
6. Views of the continuous buoy multi-parameter systems. Clock wise from top left: buoys before installation; Close-up of buoy at SMB; Buoys deployed west of SMB and I-5 Bridge locations....20
7. Views of the Aqua Troll® 400 sensor before (left) and after (right) cleaning the unit of biofouling 22
8. Example of suspect DO data collected at SMB resulting from biofouling. The final corrected data are also shown after applying a recalculation method described above....23
9. Example photos of quadrat placement. The two top photos from September 2014 survey, show placement of the quadrat on top of a sediment surface with minimal and dense macroalgae present. The bottom photo was taken from June 2015 survey, shows placement of a quadrat above mudflat “floating” conditions....32
10. Example photos of delineator placement. The right bottom photo from September 2014 (MA4) shows placement of the quadrat and delineator on top of a sediment surface that had no macroalgae present. The top right photo from June 2015 (MA3) survey photo shows placement of a delineator during a floating mudflat survey. Left photo, also from June 2015 survey (MA6), shows removal of delineator post sampling in a floating mudflat survey condition 33
11. Schematic of modified floating macroalgae transect and placement of quadrats for each survey. (*) Transect length varies from 10 to 30 m depending on total length of mudflat (seeTable 10). The red star indicates co-located sampling of benthic algae and water sampling with 0-m sampling location 33
12. Example photos of biomass survey during floating algae conditions. The left photo illustrates quadrat placement using same four transect point as illustrated in Figure 11. The right photo is a picture of the delineator filled with algae cut away from the surface. Photos were taken at MA4 in October 2015....34
13. Photos depict examples of floating transect along MA3. The left photo shows 0 and 30 m temporary markers placed along transect. The right photo shows position of 0-meter marker from ~1 m off vegetation edge 0-meter marker. Note 0-meter marker is not visible as it is underwater. The drawn lines are provided to depict the general vicinity of veg edge 36
14. Benthic algae sampling. The left photo illustrates insertion of the sediment syringe sampler into the mud while pulling up on the syringe plunger. The right photo illustrates sample at 1 cm marker post removal from sediment and use of spatula to cut off excess. Photos taken at MA3 station during October 2014 sampling event....38

15. Examples of mouth berm elevation survey data collection using a Trimble GPS with 2-m external antenna. Measurements were made while crossing the mouth when open and on dry land locations around the mouth area when closed. Two photos on the left show the estuary in a closed-mouth condition 41
16. Kayak setup for axial survey at the closed-mouth of the estuary in May 2015. Buoys off the side of the kayak were used to float the Troll sensor unit. The GPS antenna is visible at the stern 42
17. Bathymetric survey work in upper estuary. The yellow vessel is an Ocean sciences Z1800 remote control boat collecting position and water depth data. The vessel was remotely controlled by a joystick operated in the nearby kayak.....44
18. Estuarine water temperature measured at 1 m depth at the I-5 and Stuart Mesa bridges overlain with daily high air temperature data (7-day moving average) from Vista, CA.....49
19. Estuarine water salinity measured at 1 m depth at the I-5 and Stuart Mesa bridges overlain with cumulative precipitation data from Vista, CA 49
20. Annual rainfall from NOAA weather station in Vista, CA. The 2016 value (*) only includes data from only the first half of the year. The 9-year average value was 10.4” 50
21. Annual average river flow from the USGS gage at Ysidora (11046000). The last five-year average value was 15 cfs versus 53 cfs the previous five years 50
22. Salinity at SMB and estuary water elevation data at I-5 along with tides and significant wave height data during March 2016. The mouth was closed during this time frame. Water elevation in the estuary rose on the 5th, 6th, and 7th as a result of rainfall, while it rose on the 8th as a result of overtopping of the berm.....51
23. Estuarine dissolved oxygen concentrations at 1 m depth at the I-5 and Stuart Mesa bridges 51
24. Daily average of estuarine dissolved oxygen concentrations at 1 m depth at the I-5 and Stuart Mesa bridges 52
25. Daily changes in dissolved oxygen concentrations at 1 m depth at the I-5 and Stuart Mesa bridges starting 22 November 2014 52
26. Cumulative frequency of dissolved oxygen concentration values for the entire dataset (All), a subset of data during open-mouth conditions (Open), and a subset of data during closed-mouth conditions (Closed) for I-5 (top plot) and SMB (bottom plot) 53
27. Water level measured at the I-5 Bridge and NOAA predicted tides for La Jolla, CA. Water level changes show that the mouth was closed between 9 and 17 February 2015, 31 March through 23 December 2015, and again 26 February 2016 for the remainder of monitoring through June 2016.....55
28. Water levels in the ocean and estuary during a mouth-open period. Red circles indicate water level crossing times 56
29. Water levels in the ocean and estuary during a mouth-closing event. The red arrow suggests the trend in berm height at the mouth.....56

30. Water levels in the ocean and estuary along with significant wave heights observed during a closed-mouth. Overtopping of the berm by a combination of tides and waves resulted in an increase in estuary water level....57
31. Water levels in the ocean and estuary along with significant wave heights observed during a closed-mouth. Rainfall along with overtopping of the berm by waves resulted in an increase in estuary water level....57
32. Water levels in the ocean and estuary along with significant wave heights and cumulative precipitation during the mouth-opening event in December 2015....58
33. Average monthly total nitrogen measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature at each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016....66
34. Average monthly total phosphorous measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature for each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016....67
35. Average monthly total Chl-*a* measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature for each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016....68
36. Average monthly total nitrogen, rainfall, and monthly average discharge measured at the Ysidora gage. The brown highlighted region of the plot spans the timeframes of closed-mouth conditions....69
37. Total nitrogen vs. total phosphorous for all discrete water sample data collected during the 21-month monitoring period. Three points falling off the linear regression line include a sample from Lake O'Neill (yellow square), from MA6 in January 2016 (green diamond), and from SMB in April 2016 (orange circle). The Lake O'Neill sample was not included in the regression....69
38. Average total nitrogen (top), phosphorous (middle), and Chl-*a* (bottom) measured throughout the 21-month period at the six monthly discrete water monitoring stations....70
39. Total nitrogen (top), phosphorous (middle), and Chl-*a* (bottom) concentrations measured in samples taken during on the axial mapping surveys in May 2015 and June 2016. The mouth was closed during both events....71
40. Spatial distribution of TN and TP during two open-mouth conditions in January 2015 and 2016 (top plots) and during two closed-mouth conditions in September 2015 and May 2016 (bottom plots)....72
41. Examples of low (January 2015) and high (October 2015) macroalgal biomass at MA4....78
42. Average macroalgae biomass calculated for all stations during each monthly visit. The data roughly represent estuary-wide averages though not every station was represented each visit. Average monthly temperature and salinity values are also shown. Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in May 2015 or February 2016....79

43. Average monthly macroalgal biomass concentration and surface water discharge to the estuary measured at the Ysidora gage (USGS gage 11046000). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in May 2015 or February 2016 79
44. Average monthly macroalgal biomass, total nitrogen, and total phosphorous concentrations measured at all six stations throughout the estuary. Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in May 2015 or February 2016 80
45. Estuary water level and tides elevations for February 2015. The mouth closed completely for about a week starting on 10 February and slowly opened during the following week with a set of high tides 80
46. Macroalgal biomass averaged for each station during the entire monitoring period. Values depicted by the lines above each bar are the average + standard deviation 81
47. Monthly estuary-wide averaged macroalgae biomass and percent cover 82
48. Macroalgae percent cover averaged for each station over the entire monitoring period 82
49. Station averaged macroalgae biomass vs. station averaged macroalgae percent cover 83
50. Percent of possible total observations of each class of macroalgae 86
51. Spatial diversity measured as the total number of macroalgae species observed. The plot includes the average percent observed by station for the two most observed macroalgae: *Cladophora* (CLD) – green line; and *Gracilaria* (GRA) – red line. The average percent observed submerged aquatic vegetation species *Ruppia* (Rup) by station is provided as reference (yellow line) 87
52. Total number of species observations by month with the percentage of *Cladophora* observations (top). Total number of species by month with macroalgae percent cover. Brown bars indicate closed-mouth conditions while blue bars indicate open-mouth conditions. No samples were collected in May 2015, or February and April 2016 88
53. Average percent species diversity vs. average macroalgae biomass (top) and average macroalgae percent cover (bottom) across the entire estuary over time 89
54. Relative contribution of each macroalgae group to overall total observations throughout the monitoring period (September 2014 to May 2016). Note that there was no survey collection in May of 2015 and February and April of 2016. Colors within stacked bars correspond to marcoalgae key in Table 27 90
55. Relative contribution of each macroalge group to total observation per station. Colors within stacked bars correspond to marcoalgae key in Table 27 91
56. Average frequency of SAV species observed across all stations 92
57. Correlation *of Ruppia* spp. observed across estuary over time to Total Chl-*a* (top). Temporal patterns of SAV *Ruppia* spp. observations (bottom). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. Average benthic algae Chl-*a* (µg/m^2) is included for comparison. No samples were collected in May 2015 or February and May 2016 93

58. Correlation of average observations of *Ruppia* spp. measured at each station vs. macroalgae diversity (top) and macroalgae biomass (bottom) 94
59. Spatial distribution of *Ruppia* spp. observations 95
60. Monthly averaged benthic algae total chlorophyll-*a* overlain with macroalgae biomass (top) and phytoplankton chlorophyll-*a* (bottom). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions 104
61. Station averaged macroalgae biomass and benthic algae total chlorophyll-*a* measured over the entire monitoring period 105
62. Monthly averaged (estuary wide) percent cover of macroalgae, benthic algae, and submerged aquatic vegetation 105
63. Station-averaged percent cover of benthic algae, aquatic vegetation, and macroalgae....106
64. Beach berm morphology under open (two left photos) and closed (two right photos) mouth conditions 107
65. Mouth elevation surveys showing where the mouth opening was located in September 2014, March 2015, and January 2016. The red line shows the approximate mid-channel location of water flow. The white dashed line is the approximate central axis of the estuary. Elevation values are in cm NAVD88 108
66. Mouth berm height elevations in cm NAVD88. The values represent the maximum elevation where water flowed through the mouth when it was open, or the maximum dry land elevation when it was closed 108
67. Measured (red circles) and estimated (green line) berm height at the mouth based on minimum water levels measured in the estuary (blue line). Note that the September 2014 elevation was -25 cm and is shown below the plot on the left....109
68. Spatial distribution of salinity and temperature measured on 18 May 2015. Photos supplied by Google Earth 110
69. Spatial distribution of dissolved oxygen and pH measured on 18 May 2015. Photos supplied by Google Earth 111
70. Spatial distribution of salinity and temperature measured on 14 June 2016. Photos supplied by Google Earth 112
71. Spatial distribution of dissolved oxygen and pH measured on 14 June 2016. Photos supplied by Google Earth 113
72. Spatial distribution of salinity measured on 12 October 2010 114
73. Bathymetry data coverage in May 2015 115
74. Bathymetry elevation data measured in May 2015 in meters relative to mean sea level ...115
75. Bathymetry elevation data measured in March 2013 in meters relative to mean sea level 116
76. Differences in bathymetry elevation data measured in May 2015 and March 2013 (2015–2013) in meters relative to mean sea level. Photo supplied by Google Earth 116
77. Average monthly macroalgae, salinity, and temperature through the monitoring period 123
78. Average monthly macroalgae, total nitrogen, and total phosphorous through the monitoring period 123

79. Average monthly macroalgae and dissolved oxygen through the monitoring period. The complete dissolved oxygen record is overlain in background 124
80. Average monthly macroalgae biomass and total nitrogen (mg/L) along with daily rainfall totals in inches 124
81. Average macroalgal biomass vs. TN and TP at stations MA1, MA3, and MA6 125
82. Dissolved oxygen concentrations measured at the I-5 Bridge. The values shown in red are for times when DO went below 5 mg/L for more than 24 hours. This occurred on three occasions for up to 4 days 126
83. Dissolved oxygen concentrations measured at the Stuart Mesa Bridge. The values shown in red are for times when DO went below 5 mg/L for more than 24 hours. This occurred on 14 occasions for up to 7 days 127
84. Maximum monthly macroalgae biomass vs. daily minimum dissolved oxygen concentrations measured during closed-mouth conditions (blue squares). The regression line crosses 5 mg/L at a macroalgae biomass concentration of 129 g dw/m^2. The red points on the plot show data for open-mouth conditions 128
85. Average total nitrogen (top) and total phosphorous (bottom) concentrations for discrete water samples collected in 2006 and 2007 (Katz, 2007), 2010 (Katz and Rivera, 2012), 2008 and 2009 (McLaughlin et al., 2013), and 2014 through 2016 based on Table 36, above. TP was not measured in the 2007 dataset 130
86. Average macroalgae biomass (top) and macroalgae percent cover (bottom) concentrations for discrete water samples collected in 2006 and 2007 (Katz, 2007), 2010 (Katz and Rivera, 2012), 2008 and 2009 (McLaughlin et al., 2013), and 2014 through 2016 based on Table 36, above. MA was not measured in the 2007 dataset 131
87. Combination plot of total nitrogen and macroalgae biomass data as shown above in Figure 85 and Figure 86 132

Tables

1. Monitoring parameters and measurement frequency 8
2. Nominal monitoring station locations for sample collection. Levelogger® (LL) water level sensor stations are designated with “LL”. Actual locations for axial discrete stations are reported in the results section 9
3. Monthly discrete water sampling dates 14
4. Monthly benthic algae chlorophyll-*a* sampling dates 15
5. Monthly macroalgae carbon, nitrogen, and phosphorous content sampling dates 16
6. Monthly macroalgae biomass, cover, and benthic algae collection dates. Macroalgae speciation and submerged aquatic vegetation were also evaluated 17
8. Axial and bathymetry survey dates 18
9. Discrete water sample, macroalgae, and benthic algae chemical analyses performed by the Chesapeake Biological Laboratory at the University of Maryland Center for Environmental Science 28
10. Functional areas 30
11. Predetermined distances along macroalgae intertidal survey transect for MA cover (percent) and MA biomass sample collection for each month. Distances determined from random number generator 34
12. Position and elevation values measured monthly at a surveyed-in location on the Stuart Mesa Bridge. The values were used to assess GPS elevation measurement accuracy and precision. Gray cells were not included in the accuracy or precision calculations. Mouth data were adjusted by the difference in elevation on those dates and the average value calculated for all other dates. The average measured value of 5.882 m was virtually the same as the surveyed-in elevation value of 5.883 m 40
13. Axial discrete water sampling station positions for 18 May 2015 43
14. Axial discrete water sampling station positions for 14 June 2016 43
15. Summary of continuous water quality sensor data records acquired at the two bridge locations. The summary includes the total number and percentage of possible data records collected as well as the number of data records and percentage that were recalculated as described in the methods section 47
16. Summary statistics for water quality parameters measured over the 21-month monitoring period based on a final dataset when all parameter data were available from both buoys, with minor exceptions, as described above (n = 60,478). Dissolved oxygen percent saturation and salinity were calculated from a combination of temperature, specific conductivity, dissolved oxygen, and depth sensor data 48
17. Summary statistics of combined buoy datasets for closed and open-mouth conditions. None of the differences between open and closed-mouth averages were significant at the α = 95% level 48
18. Percent of data below 5 mg/L at I-5 and SMB during open and closed-mouth conditions. The overall percentage of data less than 5 mg/L was 21.1% 53

19. Discrete water monitoring results. Grayed out cells were corrected from the laboratory report as described in the methods. Blue colored cells show TDN data that had low reproducibility in sample replicate analyses as described in the methods. NA = Not analyzed. One sample result collected from Lake O'Neill (LO) is shown at the very bottom of the table 61
20. Discrete water sample summary statistics for the entire dataset, not including the sample taken from Lake O'Neill 65
21. Macroalgal biomass measured in units of g dw/m^2. The collection date represents the first of typically 2 days in which all samples were collected. Blank cells represent conditions when a sample could not be collected. No survey was conducted in May 2015 or February 2016. An "i" indicates the sample was collected using an intertidal protocol. The remainder of samples were collected using a floating protocol (see Section 2.6) 77
22. Macroalgal biomass station statistics measured over the entire monitoring period in units of g dw/m^2 78
23. Summary of macroalgal percent cover. Blank cells represent conditions when an evaluation could not be conducted 81
24. Summary of predominant types of macroalgae and submerged aquatic vegetation identified in the field. Benthic algae were not classified. A key of abbreviations is provided for use in future tables and figures 84
25. Total number of observations of macroalgae species type by station. Blue shaded cells represent three highest observations. Yellow shaded cells represent three lowest observations. The calculated Shannon Weiner Diversity Index (H) and measure of Evenness (E) are included in the table. The calculated H_{max} for the dataset was 2.49 85
26. Summary percentage of total potential monthly observations by species. The "*" indicates measurements made during intertidal surveys. Monthly count indicates number of species observed. No measurements were made in February and April 2016 86
27. Generalized macroalgae species categories. Species included in each category listed in table. Note, SAV species *Ruppia spp*. (RUP) was included for comparative purposes 90
28. Total number of SAV observations by type and station. Blue shaded cells represent highest observations. Calculated Shannon Weiner (SW) Diversity Index (H) as well as measure of Evenness (E) for each of the six sampling stations is included in the table. Calculated SW Div (H) for the entire estuary was 1.21 with (E) of 0.75. Calculated SW Diversity $(H)_{max}$ was 1.95 91
29. Benthic algae chlorophyll-*a* results 97
30. Benthic algae total chlorophyll-a, active chlorophyll-*a*, and *Phaeophytin* summary statistics for the entire dataset 99
31. Benthic algae total chlorophyll-*a*, active chlorophyll-*a*, and *Phaeophytin* summary statistics by station.[2] 100

32. Summary of benthic algae percent cover. Blank cells represent conditions when a sample could not be collected.....101
33. Summary of submerged aquatic vegetation percent cover. Blank cells represent conditions when a sample could not be collected.....102
34. Statistical summary of benthic algae chlorophyll-*a* percent cover.....103
35. Statistical summary of submerged aquatic vegetation percent cover.....103
36. Average total nitrogen, total phosphorous, macroalgae biomass and cover for samples collected in 2006 and 2007 (Katz, 2007), 2008 and 2009 (McLaughlin et al., 2013), 2010, (Katz and Rivera, 2012), and 2014 through 2016. NA = not measured.....129

1. INTRODUCTION

This report describes current water quality conditions in the Santa Margarita Estuary monitored over a 21-month period between September 2014 and June 2016. The data collection was designed to assess current water quality conditions as they relate to eutrophication as well as compare to historical monitoring datasets collected over the past 10 years. The data were collected by the Navy's Environmental Sciences Branch of the Space and Naval Warfare Systems Center Pacific (SSC Pacific) for Environmental Security, Marine Corps Base Camp Pendleton (MCBCP). The report describes the background, technical approach, methods, and results of the data collected with a summary and analysis of water quality and the dynamics and main physiochemical processes that control it.

1.1 BACKGROUND

The Santa Margarita Estuary was listed as impaired for eutrophication by the San Diego Regional Water Quality Control Board (SDRWQCB) in 1986. This led to an investigative order in 2006 (R9-2006-076, SDRWQCB, 2006) to obtain water quality data that would be used to evaluate the extent of impairment as well as provide sufficient data for developing watershed and estuary numerical models for managing estuary water quality through implementation of a Total Maximum Daily Load (TMDL) program. The Southern California Coastal Water Research Project (SCCWRP), under contract to the SDRWQCB and with the help of multiple estuary stakeholders, generated a San Diego Coastal Lagoons TMDL Monitoring Workplan (McLaughlin, Sutula, and Schiff; 2007). That workplan outlined the technical approach, methods, and data requirements to meet the investigative order's goals. The investigative order was amended in June 2007 to alter the original goals and data requirements to those identified in the workplan.

The order led to the formation of a stakeholder group in 2007 comprised of dischargers named in the order including Marine Corps Base Camp Pendleton, City of Temecula, City of Murrieta, County of Riverside, County of San Diego, California Department of Transportation, and Naval Weapons Station-Fallbrook. While the group was forming, MCBCP had the Environmental Sciences Branch of SSC Pacific conduct some initial water quality surveys in October 2006 and (Katz, 2007). The stakeholder group, facilitated by the Bureau of Reclamation, acquired data for the order between January and December 2008 (CDM, 2009). Additional data were collected by SCCWRP between 2008 and 2009 and as part of the investigative order and under a California Bight 2008 Regional Monitoring Survey (SCCWRP, 2013). Because of gaps in the CDM dataset, the stakeholders had SSC Pacific conduct additional monitoring between 2010 and 2011 to complete the data requirements in the investigative order (Katz and Rivera, 2012).

The initial plan by the SDRWQCB, with United States Environmental Protection Agency (USEPA) support, was to utilize the water quality datasets collected under the investigative order to calibrate both watershed and water quality models for each estuary along the southern California coastline to develop load and waste load allocations under a TMDL. Though watershed modeling of the Santa Margarita River advanced, there were insufficient funds to complete the estuary water quality modeling. MCBCP therefore moved forward in late 2011 to have SSC Pacific develop and calibrate a linked hydrodynamic and water quality model of the estuary. At roughly the same time the State of California was moving forward with plans to develop the use of Nutrient Numeric Endpoints (NNE) to provide a more robust alternative to the total nitrogen and phosphorous numerical objectives utilized for assessing eutrophication under the Board's Basin Plan (SDRWQCB, 1994). The stakeholder group re-formed to address the application of the NNE to the estuary TMDL

process, as well as to generate funding grants to the state to address watershed-wide water quality assessment and monitoring.

The stakeholder group is currently in negotiations with the SDRWQCB to formulate an alternative TMDL based on numeric objectives under a NNE framework as well as to develop future monitoring requirements to meet them. The primary data used to develop benchmarks were derived from data collected under the investigative order in 2008 and 2009, as well as estuary hydrodynamic and water quality modeling (Wang et al., 2016) and its interpretation developed under a model application report (SCCWRP, 2016). The objectives and monitoring requirements are expected to be finalized early in 2017. The benchmark objectives will include primary numeric targets for macroalgal biomass in lieu of nutrient concentrations and dissolved oxygen. Additional secondary benchmarks under consideration include benthic community condition and macroalgal percent cover.

The monitoring conducted in 2014 through 2016 presented in this report provides an update to water quality conditions measured previously. On their own, the data provide insight on many of the important processes occurring in the estuary that control their distribution such as seasonal climate changes in freshwater and groundwater inputs, diel sunlight cycles, and ocean exchange. This comprehensive dataset can also be used to update the recently completed linked hydrodynamic and water quality model calibration given interest and the necessary resources. The dataset should also inform the stakeholders and Regional Board on the methods, manner, and limitations in conducting future monitoring to meet TMDL compliance benchmarks and provide a basis for evaluating future data and success of TMDL implementation.

1.2 LOCATION

The Santa Margarita Watershed encompasses approximately 750 square miles in northern San Diego and southwestern Riverside counties. The Santa Margarita River forms near the City of Temecula in Riverside County at the confluence of the Temecula and Murrieta creek systems, one of the fastest growing areas in California. Once formed, the majority of the Santa Margarita River main stem flows within San Diego County through unincorporated areas, the community of Fallbrook, and MCBCP. Additional tributaries feeding the river include Sandia, De Luz, and Rainbow Creeks. The river forms up into an estuary where it meets the Pacific Ocean just north of Oceanside, California (Figure 1).

The estuary sits entirely within the boundaries of MCBCP (Figure 2). The western boundary of the estuary is the beach berm that borders the ocean. The estuary is usually open to the ocean through a limited section of the berm, although there are occasions when the estuary is effectively closed to exchange with the ocean. The eastern boundary of the estuary is defined by the easternmost extent of maximum tidal influence. Though the exact location where this occurs is not accurately known, it does extend at least a mile northeast of the Stuart Mesa Bridge.

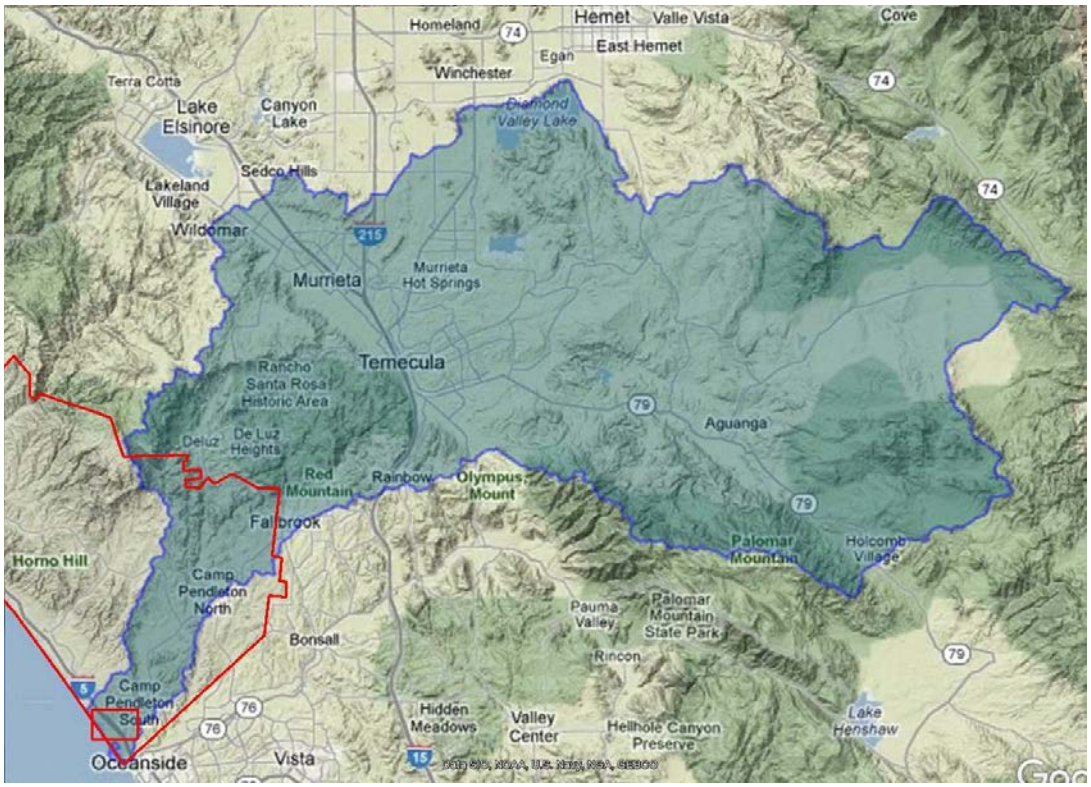

Figure 1. Santa Margarita River Watershed. The estuary is at the southwestern end of the watershed within Marine Corps Base Camp Pendleton north of Oceanside, California. Photo supplied by Google Earth.

Figure 2. Field work domain for Santa Margarita Estuary monitoring. Four bridges: north and southbound Interstate Highway I-5; North County Transit District Railroad Bridge; and Stuart Mesa Road Bridge cross over the estuary and provide key geographical landmarks for the study.

1.3 PHYSICAL SETTING

The estuary is a fairly linear water body that extends approximately 2.4 miles along its longitudinal axis to the northeast from the ocean. The perennial wetted portion of the estuary is roughly 98 acres. It is ~ 0.6 mi at its widest point along its western edge but rapidly narrows to about $1/10^{th}$ that distance at the Interstate Highway 5 (I-5) bridges. The estuary continues to narrow to the northeast and can be as narrow as 20 feet across in the upper reaches. The estuary is very shallow with water depths commonly less than 1 meter. Water depths range up to ~5 m under the bridges presumably as a result of scouring. A large portion of the western estuary is not wetted at low tide or has water depths of only a few inches deep. The bathymetry of the estuary was measured by SSC Pacific to provide this key physical domain data for hydrodynamic modeling in 2013 and again as part of this most recent monitoring in 2015. The bathymetry data collection and results from the two years is discussed in the Section 3 Results.

The estuary is subject to near year-round inflow of freshwater from Santa Margarita River, averaging 5.5 cubic feet per second (cfs) based on the United States Geological Survey (USGS) gage data collected about 5 miles upstream (USGS gage 11046000). Maximum inflows occur during winter storms where maximum flows have reached as high as 44,000 cfs. Surface water flows can diminish to zero during the summer dry period as confirmed by visual observations (Kyle Cook, personal communication). The recent hydrodynamic modeling results identified and confirmed that there is still a groundwater flow into the estuary from the watershed even during these occasions.

When open to the ocean, the estuary is influenced by semi-diurnal tides that typically result in two high and two low water periods a day. During this time, the ocean can have strong influence on estuary hydrodynamics and basic water quality parameters. Previous monitoring of water quality in the estuary (Katz, 2007) showed that this ocean influence results in a steep longitudinal gradient in water quality parameters in the vicinity of the I-5 bridges that can be thought of as a transition from a western ocean-dominated lower estuary segment to an eastern river-dominated upper estuary segment.

The estuary does not always have a connection to the ocean through the beach berm. Historical gage data collected near the railroad bridge between 1981 and 2010 (USGS Gage11046050) show that the mouth is essentially closed to the ocean (< 0.1 ft change in water elevation) 22% of the time. The size, depth, and location of the opening through the beach berm is in constant flux as a result of competing forces of freshwater flow through the estuary and wave action and long-shore drift along the beach. The beach berm tends to increase in height through the summer dry period reducing the overall amount of tidal exchange with the estuary, even if it remains open. The mouth can be opened or enlarged very quickly during large winter storms. The most recent dataset showed that when the mouth is effectively closed from exchange, the highest spring tides can overtop the berm, adding ocean water to the estuary and raising its level.

The sediments of the estuary are composed primarily of sand with silt. Three locations sampled in the lower estuary, approximately half a mile west of the I-5 bridges, had sediment grain size ranges of 50 to 86% sand, 7 to 54% silt, and 1–10% clay (CDM, 2014–2017)[1]. The average values were 65.5, 29.7, and 4.9% sand, silt, and clay, respectively. Total organic carbon (TOC) measured at these three locations were relatively low in (TOC), averaging about 0.3%. Anecdotal visual observations suggest that finer grained sediments with higher TOC tend to deposit closer in to the shorelines.

[1] Five reports were delivered as part of a report prepared for Camp Pendleton Marine Corps Base, Oceanside, CA. The reports cover the years 2012–2017 as shown below:
Accord MACTEC Joint Venture. Contract Number 5012-10-7008. 2012. "2010–2011 Municipal Stormwater Monitoring Annual Report."

2017. "2015–2016 Annual Report Municipal Watershed Stormwater and Compliance Requirements."

2. METHODS

2.1 TECHNICAL APPROACH

The technical approach was designed to collect key water quality parameters at the spatial and temporal scales that would capture the dynamic nature of the estuary both hydrographically and biochemically in response to nutrients in the form of algal production and dissolved oxygen. The approach generally expanded on the parameters, measurement frequency, and quality assurance (QA) elements developed for the investigative order by the Southern California Coastal Water Research Project (McLaughlin, Sutula and Schiff, 2007). These elements primarily included continuous measurements to capture tidal and diel processes and monthly discrete measurements to capture seasonal variations. The original goal was to collect data over an 18-month period but the timeframe was extended an additional four months in an attempt to capture the reopening of the estuary after it closed between March and December 2015.

The main field sampling elements are summarized in Table 1. Nominal station locations for each sample type are shown in Table 2 and Figure 3 through Figure 5. Two real-time buoy sensor systems were deployed at the I-5 and Stuart Mesa bridges to measure temperature, conductivity/salinity, pH, and dissolved oxygen at 15-minute intervals. Solinst® levelogger® (LL) sensors were deployed at the two bridges and near the macroalgae (MA) monitoring station (MA6) further upstream to continuously measure water level at 15-minute intervals. These data were collected because a USGS tide gage previously located at the Railroad Bridge was removed in 2010.

Discrete water samples were collected monthly at the ocean, the two bridge locations, and at three of the macroalgae stations (MA1, MA3, and MA6) and analyzed for a suite of nutrients, chlorophyll-*a* (Chl-*a)* (a measure of phytoplankton abundance), and total suspended solids (TSS). Macroalgal biomass, cover, speciation, and benthic algae (BA) Chl-*a* were sampled monthly at six intertidal stations along the shoreline. A qualitative assessment of subtidal macroalgae cover, speciation, and submerged aquatic vegetation (SAV) was also conducted at three locations between stations MA1 and MA3 and at three locations between MA4 and MA5 though these data will be reported separately. The beach berm elevation at the mouth was also monitored monthly. Two axial mapping surveys were performed from the mouth to the upper reach of the estuary by kayak. Discrete water samples were collected from 11 stations along the axial track and from the ocean (at a slightly different location than the monthly monitoring site). A bathymetric survey of the estuary was also completed once during the monitoring period.

Several additional ancillary datasets were collected during the monitoring timeframe that provide key information though they were not collected directly as part of this study. SSC Pacific quantified groundwater entering into the estuary from the historical agricultural fields on the northern shore near to MA2 and the I-5 Bridge on multiple occasions during the period. These data have been previously quantified in the estuary since 2010 and summarized in (Leather, Guerrero, Katz, and Chadwick, 2015 and 2016). Storm water was sampled during the timeframe and for the past ten years as part of the Base's normal Municipal Separate Storm Sewer System monitoring program. SCCWRP also collected nutrient, benthic algae and hydrographic data in the in the lower Santa Margarita River throughout 2015 and 2016 (unpublished).

Additional data used in assessing historical conditions and trends include: a 35-year historical record of water level to assess mouth closure and ~20 years of temperature, conductivity, and dissolved oxygen, and pH data (USGS gage 11046050); historic and recent river flow just upstream of the estuary at the Ysidora (USGS gage 11046000). Tide data from the National Oceanic and Atmospheric Administration's (NOAA) La Jolla Tide gage 9410230 to evaluate expected water levels in the estuary during the period; and historic and current rainfall and temperature data from NOAA's weather station at Vista, California (http://www.wrh.noaa.gov/sgx/obs/rtp/vista.html).

Table 1. Monitoring parameters and measurement frequency.

Parameter	Measurement Frequency
Sensor Buoy I-5 Bridge	Continuous at 15 min
Sensor Buoy Stuart Mesa Bridge	
Water Level I-5 Bridge	
Water Level Stuart Mesa Bridge	
Water Level Station MA6	
Discrete Water Samples 6 Stations	Monthly
Quantitative Macroalgal Biomass, Cover, and Speciation, Qualitative Submerged Aquatic Vegetation at 6 Stations	
Benthic Algae Chl-*a* at 6 Stations	
Mouth Berm Height Survey	
Axial Survey with Discrete Water at12 Stations	Twice
Bathymetry Survey	Once

Table 2. Nominal monitoring station locations for sample collection. Levelogger® (LL) water level sensor stations are designated with “LL”. Actual locations for axial discrete stations are reported in the results section.

Station	Sample Type	Longitude W	Latitude N
I-5 Buoy	Continuous Sensor, Water	117.407083	33.235517
SMB Buoy	Continuous Sensor, Water	117.395160	33.237662
I-5 LL	Continuous Sensor	117.406033	33.235800

Figure 3. Continuous water quality sensor buoy and water level (LL) station locations. The buoys were ~ 10 m downstream of the bridge pilings. The aerial was collected when the mouth was fully closed in March 2016. A barologger unit (not shown above) was located directly on shore underneath the I-5 Bridge southbound lanes.

Figure 4. Monthly monitoring stations. Six macroalgal biomass and cover and benthic algae intertidal station locations: MA1, MA2, MA3, MA4, MA5, and MA6. Discrete water samples for nutrients, TSS, and Chl-*a* were collected monthly at the Ocean, MA1, MA3, MA6, and the I-5 and Stuart Mesa Bridges.

Figure 5. Nominal axial mapping survey transect between the ocean and the most northeastern portion of the estuary reachable by kayak from the west. Discrete water samples were collected at 11 station locations along the transect as well as in the ocean. The ocean station was ~ 500m south of the normal monthly sampling location. Axial stations 4 and 7 were collected at the I-5 and Stuart Mesa Bridge buoys, respectively.

2.2 GENERAL PROJECT CHRONOLOGY

Field data collection began in the estuary starting on 9 September 2014 with the installation of the real-time continuous monitoring sensor buoy and level logger at the I-5 Bridge and a survey of the mouth berm height. A buoy system and level logger were installed the next day at the Stuart Mesa Bridge. With minor exceptions, sensor data were continuously collected throughout the subsequent 21-month period ending on 14 June 2016. The exceptions included short periods (1 to 2 hours) each month (sometimes semi-monthly) during sensor calibration checks and during a 3-day period from 2 through 5 December 2014 when the buoy systems were pulled out of the water in anticipation of a very large storm and flow event.

Monthly sampling dates were primarily driven by the requirement to collect algal biomass and berm height data during daylight lower low-tide conditions. NOAA predicted tide tables for La Jolla (http://tidesandcurrents.noaa.gov/noaatidepredictions/NOAATidesFacade.jsp?Stationid=9410230) were used to identify potential dates having the lowest tides of the month. Sensor calibrations, level sensor data downloads, water sampling, and mouth berm height surveys were typically completed on the day before or after the algal biomass and benthic algae sampling. Monthly sampling dates are shown in Table 3 through Table 8. Small variations in the monthly schedule occurred on occasion to meet logistical or personnel availability constraints. In particular, macroalgal biomass sampling was not conducted in May 2015 and instead, was conducted twice in June. Algal and discrete water sampling was not conducted in February 2016 because of limited project resources after extending the project duration. Survey of the mouth berm height in April 2016 (closed condition) was also not completed for the same reason.

The estuary was open to the ocean when monitoring began in September 2014. For the next several months the opening moved northward and the berm height increased when it became fully closed on 31 March 2015 (there was also a one-week closure in mid-February 2015). It remained fully closed until 23 December 2015 when storm flow and ocean conditions resulted in its reopening to the south. The mouth remained open until 26 February 2016 when it closed again for the duration of the monitoring. Flow through the mouth and water elevation changes were relatively restricted even when the mouth was open. The result was that actual lower low water levels were delayed for up to three or four hours relative to the predicted tide and the lower low tide conditions was rarely observed. The time delay and lack of lower low tide impacted the ability to accurately plan and sample intertidal macroalgae biomass during weekday daylight hours even when the mouth was open. The result was that low water conditions in the estuary were rarely observed when expected and macroalgae sampling was almost always measured under wetted conditions. Complete results of the water level and berm height measurements are described later in Section 3.

2.3 CONTINUOUS WATER QUALITY

2.3.1 Data Collection

Continuous water quality parameters were collected at the two bridges using an Aqua Troll® 400 multi-parameter sensor unit from In-Situ, Inc. The units were equipped with optical dissolved oxygen, pH, conductivity, temperature, and depth sensors. Dissolved oxygen (DO) data were reported in concentrations units of mg/L as well as percent saturation based on a calculated equilibration concentration with the atmosphere for the measured depth, conductivity, and temperature. Conductivity, temperature, and depth data were also used to calculate sample salinity.

The units were installed on Fondriest/Nexsens MB-150 solar-powered buoys, each with Nexsens SDL500 submersible data logger and cellular connection. The buoys were positioned downstream from the southbound I-5 and Stuart Mesa Bridges as shown in Figure 6. The Aqua Toll units were suspended 1 m below the surface from the buoy inside a 3" perforated PVC pipe used for protection.

Water quality data were collected throughout the 21-month monitoring period with the exception of three days in December 2014 when the buoys were removed in anticipation of a large rain event. Specifically, the I-5 unit collected data between 15 September 2014 and 14 June 2016, while the SMB unit collected data between 11 September 2014 and 14 June 2016. All data were collected at 15-minute intervals by performing measurements once every 5-minutes and recording the average of three measurements.

Data from the two systems was monitored daily using a cellular phone connection with iChart 6 software from Nexsens Technology. The information collected from both units was reviewed daily and updated into a single datafile. This daily update ensured that the systems were operational and working within expected parameters and allowed problems to be quickly identified and corrected as described below.

2.3.2 Sensor Calibration

Verification of sensor operational conditions and calibration was performed during each monthly site visit. However, there were occasions when one or more of the sensors appeared to have a lowered response as a result of fouling when reviewing the daily updates. The lower response was usually identified only after the low response trended for several days. On these occasions an extra site visit was made to check and recalibrate the sensors.

The response of the sensor electrodes was verified on site with calibration standards and procedures recommended by the manufacturer using In Situ's CommKit software program. The first step was to evaluate the sensor responses prior to cleaning the sensors of fouling organisms. The DO sensor was checked with air sparged 18 Mega-ohm/cm water (100% dissolved oxygen) and with a saturated sodium bisulfite in 18 Mega-ohm/cm water (0% dissolved oxygen).The pH sensor was checked against buffers of pH 7.0 and 10.0, while the conductivity sensor was checked with a 58,760 µS/cm specific conductivity at 25° C standard. Each reading generally equilibrated in about two minutes or less, and the final measurement was recorded in the field notebook.

The second step in the process was to clean all the sensors using brushes to remove major particles, and detergent and/or weak (~5%) hydrochloric acid solution to dissolve calcareous deposits. The sensors were then thoroughly rinsed with18 Mega-ohm/cm deionized water and rechecked for calibration using the procedures described above. A calibration was considered acceptable if the sensor response was ≤5% of the calibration standards. Individual sensors were recalibrated if they were outside the range of acceptability and the information was record in the field notebook. In general, cleaning the sensors brought their calibration back within acceptable limits. The calibration tables and field data logs are provided in the appendices.

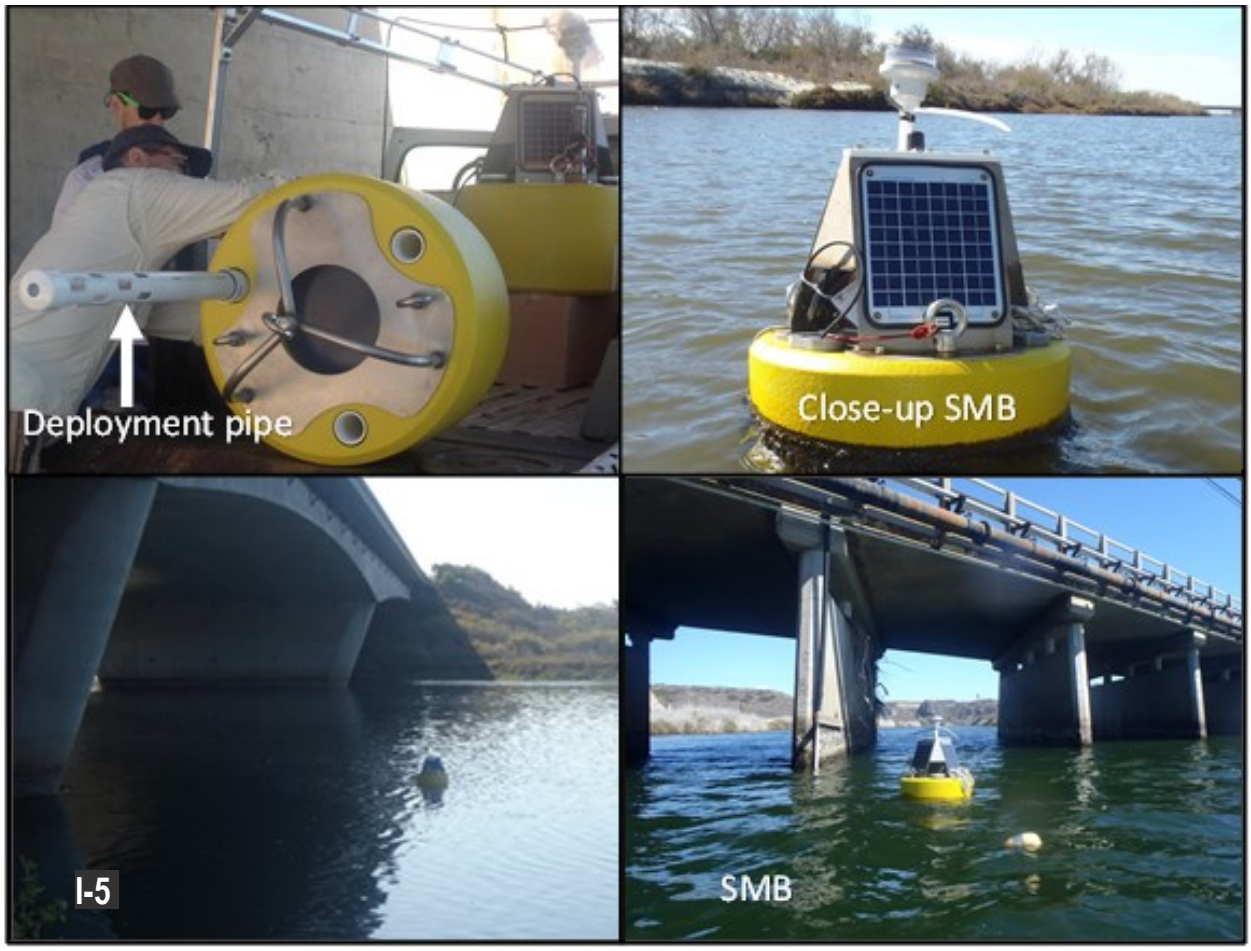

Figure 6. Views of the continuous buoy multi-parameter systems. Clock wise from top left: buoys before installation; Close-up of buoy at SMB; Buoys deployed west of SMB and I-5 Bridge locations.

2.3.3 Data QA/QC

There were instances when the continuous water quality data, particularly measurements of DO and conductivity, were considered suspect as a result of fouling. Fouling was generally more severe than observed in 2011 because of the very low or no flow conditions in the estuary when the mouth was closed. Fouling was also generally higher at the SMB location than at the I-5 Bridge location. The result was that the sensor surfaces would become encrusted with algae and other organisms that impacted the accuracy of the sensor measurement Figure 7). An attempt was made to adjust for the impacts of this using best professional judgement to identify the suspect data and using a time-weighted correction algorithm to correct the values.

An example of suspect data and the result of correcting it are presented in Figure 8. The figure shows data measured at SMB Bridge from 21 April 2016 to 31 May 2016. There are two periods of time when the dissolved oxygen electrode provided data considered suspect. Calibration verification performed on 12 and 24 May 2016 showed that the dissolved oxygen sensor was reading low before cleaning and came into calibration once it was cleaned.

Professional judgement was used in order to figure out the extent of data considered suspect, with an effort in limiting the amount of recalculated data. In most instances, sensors at only one of the two buoys was impacted, indicating that it was mostly likely a sensor issue as opposed to a general

change in estuarine conditions. Instead of recalculating all the data between two consecutive calibration verifications, an effort was made to estimate when the data had deviated the most from the general trends in the dataset. The difference in measured values before (CV_{-1}) and after calibration verification (CV_{+1}) was divided by the total number of associated suspected data (T^{th}) to calculate a deviation factor. This factor was then multiplied by the consecutive order number of each data point ($N_S{}^{th}$), starting with the oldest data point, and added to the measured value ($S_d{}^{th}$). This correction provides a linear but proportionally larger correction factor to the data closest to the calibration verification, and a proportionally minimal factor for the older data. The formula used for recalculation is as follows:

$$R_d^{th} = S_d^{th} + \left[\left(\frac{CV_{+1} - CV_{-1}}{T^{th}}\right) \times N_S^{th}\right]$$

where:

$R_d{}^{th}$ is the "nth" recalculated data

$S_d{}^{th}$ is the "nth" suspected data

CV_{+1} is the first data measured after calibration verification

CV_{-1} is the last data measured before calibration verification

T^{th} is the total number of suspected data points

$N_S{}^{th}$ is the order number for each suspected data point starting with the first and older suspected data

The outcome of the recalculation can be seen to preserve the general temporal trends in the example dataset in Figure 8. The recalculated data were also compared to observations at the other buoy to ensure that the corrected data were consistent with the general trends observed there. Overall, the recalculation method was applied to 11.2% and 21.5% of conductivity and DO data, respectively at the I-5 Bridge. Similarly, the recalculation of data at SMB was 29.5% and 18.1 for conductivity and DO data, respectively. About 1.5% of the dissolved oxygen data could not be corrected using the recalculation method and were left out of the final reporting. The final dataset with both the original data and recalculations are presented in the appendices.

Though the sensor data were reported daily by cellular connection, it remained a difficult task to determine if a trend in the data was natural or related to fouling. It usually took several days to get a sense that the data were affected by conditions. The extent of fouling led to increasing the frequency of the calibration checks to biweekly. The higher frequency is recommended to improve the likelihood of fouling impacts. Though more frequent visits should improve the results, the general issue of low flow around the sensor can still to be an issue in properly quantifying low DO values. Since low values are a key metric for evaluating water quality, consideration should be given to using an additional sensor to test water column DO at multiple nearby locations to validate the concentrations during calibrations or conducting additional simultaneous measurements that are offset in their calibration times.

Figure 7. Views of the Aqua Troll® 400 sensor before (left) and after (right) cleaning the unit of biofouling.

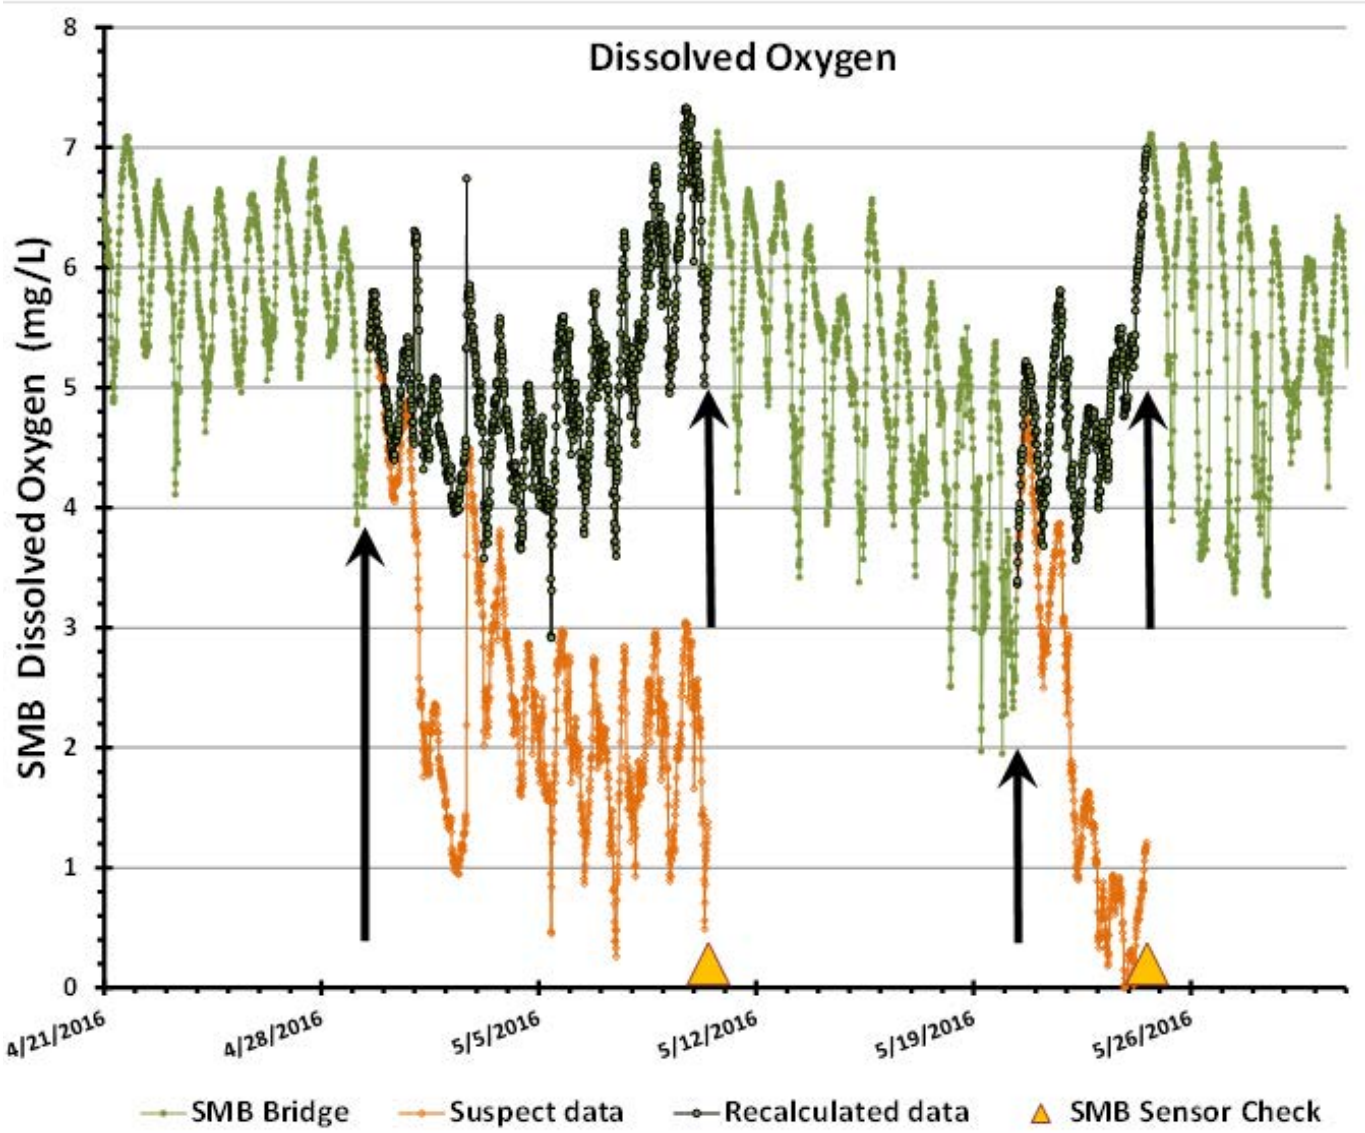

Figure 8. Example of suspect DO data collected at SMB resulting from biofouling. The final corrected data are also shown after applying a recalculation method described above.

2.4 CONTINUOUS WATER LEVEL

2.4.1 Data Collection

Water level was measured at three locations (I-5, SMB, and MA6) using a Solinst® Model 3001 Levelogger®. The units are self-logging level sensors measuring total pressure of water and air above the sensor. The sensors were placed ~3 to 6' below the water surface and set to make a measurement every 15 minutes. The senor unit at I-5 was placed into a 3" diameter PVC pipe that was pounded into the bottom ~70 m upstream of the bridge. The top of the pipe was surveyed-in for position and elevation in 2013 (Kappa, 2013). The levelogger® at SMB was placed into a 3" diameter PVS pipe attached to one of the bridge pilings. The level logger at MA6 was attached to a concrete block placed on the bottom. A barometric pressure logger was placed on shore directly under the I-5 southbound bridge.

A Solinst® barologger unit was placed under the I-5 Bridge to measure barometric pressure, which was used to correct the Levelogger® data to obtain absolute water levels. The main purpose of using three units was to determine if there was significant phase lag up the estuary and to provide redundant measurements in case a unit failed. On two occasions sensors were replaced because they failed after the unit's outer body corroded through.

2.4.2 Data Processing and QA/QC

Level and barometric pressure data were downloaded during monthly visits using a Solinst® optical data reader. Absolute water level data were calculated using the measured level and barometric pressure datasets with Solinst® Levelogger® Software version 4.1.0. The corrected data were exported to Microsoft Excel for displaying and conducting data evaluation. See the appendices for more information.

Data QA/QC

Level calibration checks were made when the units were installed and periodically throughout the monitoring period to evaluate the absolute measured level values against depth measured with a ruler or tape. Measurements generally agreed within 1 cm, a value that was considered acceptable and did not require further calibration.

2.5 MONTHLY DISCRETE WATER

2.5.1 Sample Collection

Discrete water samples were collected monthly in the Ocean, at MA1, MA3, MA6 and the two bridge locations and analyzed for a suite of nutrients, phytoplankton Chl-*a*, and total suspended solids. Water samples were also collected in the Ocean and at11 additional locations along an axial mapping survey transect in May 2015 and June 2016 as described in Section 2.9. One additional sample was collected in September 2015 at the southwest outflow area of Lake O'Neill, approximately 12 km upstream from the estuary. Water depths at the MA stations were ~ 0.5m or less while water depths at the two bridge locations were roughly 6 m. The ocean sample was taken in approximately 1 m. The same collection method (except for the ocean sample) and analytical procedures were used for all samples.

Water samples in the estuary were collected by hand with nitrile gloves at a depth of approximately 0.3 m. This was usually done from a kayak by dipping three separate pre-cleaned 1-L amber glass bottles below the water surface, rinsing twice with estuary water, and filling them to the top. MA1 and MA3 water samples were collected downstream of the sediment and macroalgae collection and co-located near the end of 0-meter macroalgae transect marker. MA6 water samples

were collected ~ 1 m from continuous water sampling sensor and co-located with sediment sampling. Ocean water samples were collected by walking into waist-high water in the surf zone with a pre-rinsed plastic bucket. The bucket was rinsed at least three times with ocean water before collecting a ¾-full bucket sample that was brought back to shore to rinse and fill three 1-L amber glass bottles by dipping their mouths below the surface. The bottles had previously been soaked in diluted phosphate-free detergent for at least one day then copiously rinsed with18 Mega-ohm/cm deionized water. The samples were kept in the dark and on ice in coolers until processed at the SSC Pacific laboratory.

When conditions were favorable for collection along the mudflats, water samples at stations MA1, MA3, and MA6 were collected approximately 1 m downstream of the vegetation edge at a depth of approximately 0.3 m and co-located near both sediment collection and the end of 0-meter macroalgae transect marker. Occasionally samples had to be collected after leaving the kayak and walking a short distance to the collection site. In these instances water samples were collected after resuspended sediments were allowed to settle. The ocean sample was also subject to resuspended sediments as a result of the surf. Sediments in the bucket were allowed to settle before filling the bottles. The single sample collected at Lake O'Neill was collected with the same methods described for estuary samples.

2.5.2 Sample Processing and Analysis

Water samples were processed by scientific staff at SSC Pacific laboratories in accordance with methods provided by the Chesapeake Biological Laboratory at the University of Maryland Center for Environmental Science, the lab that conducted all of the chemical analyses (Table 9). Aliquots of water samples were transferred to small polyethylene bottles for total nutrient analyses. All transfers were made after rinsing with sample water and while wearing nitrile gloves. Aliquots were also filtered through pre-weighed glass fiber filters to generate samples for both particulate and dissolved phase nutrient analyses. Separate aliquots of water sample were also filtered for Chl-*a* and total suspended sediments. All water and filters were kept frozen at -20°C until they were analyzed at the laboratory. All processing was conducted with pre-cleaned bottles and filtration equipment.

Brief methods for each analyte are described below. The full methods can be found on the Chesapeake Biological Laboratory website (http://www.nasl.cbl.umces.edu/methods/WCC.html).

Nitrite (NO2-N)-USEPA Method 353.2 (USEPA, 1993a). Filtered water samples were diazotized with sulfanilamide and coupled with N-1-napthylethylenediamine dihydrochloride to form a colored azo dye, yielding an intense pink color suitable for photometric measurement.

Ammonia (NH4-N)-USEPA Method 350.1 (USEPA, 1993b). Filtered water samples were complexed with sodium potassium tartrate and sodium citrate. The complexed sample was reacted with alkaline phenol and hypochlorite, catalyzed by sodium nitroprusside, yielding an intense blue color suitable for photometric measurement.

Nitrate and nitrite (NO3+NO2-N)-USEPA Method 353.2 (USEPA, 1993a). Filtered samples were passed through a granulated copper-cadmium column to reduce nitrate to nitrite. The nitrite, both that which was reduced from nitrate and nitrite that was originally present, was then determined by diazotizing with sulfanilamide and coupling with N-1- napthylethylenediamine dihydrochloride to form a colored azo dye.

Dissolved Nitrogen (DN)-USEPA Method 353.2 (USEPA, 1993a). An exact amount of filtered sample was placed in test tubes where an exact amount of Potassium Persulfate Digestion Reagent was added. Under initially alkaline conditions and heat, nitrate is the sole nitrogen product. The digested sample was buffered, then mixed and passed through a granulated copper-cadmium column to reduce nitrate to nitrite. The nitrite, both that which was reduced from nitrate and originally

present, is then determined by diazotizing with sulfanilamide and coupling with N-1-napthylethylenediamine dihydrochloride to form a colored azo dye.

Particulate Nitrogen (PN) and Particulate Carbon (PC)-USEPA Method 440.0 (USEPA, 1997a). The carbon and nitrogen content in organic and inorganic compounds was determined after combustion of the sample in pure oxygen under static conditions. The products of combustion are passed over suitable reagents in the combustion tube to assure complete oxidation and removal of undesirable by-products such as sulfur, phosphorus and halogen gases. In the reduction tube, oxides of nitrogen were converted to molecular nitrogen and residual oxygen was removed. The mixture was released through the sample volume into a set of thermal conductivity detectors accounting for hydrogen and carbon dioxide generated in the sample and providing separate measures of nitrogen and carbon.

Total Nitrogen (TN)-USEPA Method 353.2 (USEPA, 1993a). Total nitrogen was measured with the exact same method as dissolved nitrogen except it was made on the unfiltered water sample.

Phosphate (PO4-P)-USEPA Method 365.1(USEPA, 1993c). Filtered water samples were mixed with a sulfuric acid-antimony-molybdate solution, and subsequently with an ascorbic acid solution, yielding an intense blue color suitable for photometric measurement.

Particulate Phosphorous (PP)-USEPA Method 365.1 (USEPA, 1993c). Filtered samples were combusted, then extracted in an acidic medium. Particulate inorganic phosphorus was extracted in an acidic medium and the extracted sample was mixed with a sulfuric acid-antimony-molybdate solution, and subsequently with an ascorbic acid solution, yielding an intense blue color suitable for photometric measurement.

Dissolved Phosphorous (DP)-USEPA Method 365.1(USEPA, 1993c). An exact amount of filtered water sample was placed in test tubes where an exact amount of Potassium Persulfate Digestion Reagent was added. Under initially alkaline conditions and heat, nitrate is the sole nitrogen product. As the potassium persulfate continues to oxidize, conditions become acidic and orthophosphate becomes the sole phosphorus product. The digested sample was buffered, then mixed with a sulfuric acid-molybdate solution, and subsequently with an ascorbic acid solution, yielding an intense blue color suitable for photometric measurement.

Total Phosphorous (TP)-USEPA Method 365.1 (USEPA, 1993c). Total nitrogen was measured with the exact same method as dissolved nitrogen except it was made on the unfiltered water sample.

Total Suspended Solids (TSS)-USEPA Method 160.2 (USEPA, 1971). A filtered sample was placed into a 105° C drying oven overnight to remove any remaining water. The filter pads were removed from the oven and placed into a desiccator to cool to room temperature. Once samples reached room temperature, they were individually weighed on a four place balance and their respective weights measured. The amount of particles was calculated as the difference between the sample+filter weight and the filter weight measured before filtration.

Total Chlorophyll-*a* (Total Chl-*a*)-USEPA 445.0, SM10200H.3 (USEPA, 1997b). Chlorophyll was extracted from filtered sample using a 90% solution of acetone. The samples were refrigerated in the dark from 2 to 24 hours. The samples were then allowed to come to room temperature and then centrifuged to separate the sample material from the extract. The extract was analyzed on a fluorometer.

Active Chlorophyll-*a* (Active Chl-*a*) and Phaeophytin (Phaeo). The concentrations of active Chl-*a* and phaeophytin were determined after the Chl-*a* extract described above was acidified with 5% hydrochloric acid.

2.5.3 Analysis QA/QC

Sample collection and processing procedures included using gloves, pre-cleaned bottles, sampling equipment, and pre-rinsing all materials with sample water prior to capture. Samples were stored in the dark on ice and processed within 24 hours of collection in clean laboratory conditions to ensure consistency and less chance of contamination. All processed samples were kept frozen until analysis.

A continuous-flow analytical technique was used for analysis of nitrate+nitrate, nitrite, ammonium, chloride, sulfate, nitrogen, and phosphates/phosphorus. Standards were made from appropriate dry reagents and calibrating standard solutions were run in each analytical batch. Laboratory duplicates, laboratory spikes, control samples, and documentation of the response slope were also used for quality assurance. The Chesapeake Biological Laboratory Nutrient Analytical Services Laboratory also participates in cross-calibration exercises, as part of Good Laboratory Practices standards, to ensure laboratory performance. Standard operating procedures for these analyses can be found on the lab website (http://www.nasl.cbl.umces.edu/). Sample duplicate and spiked analyses of nutrients were all within 10% except for total dissolved nitrogen analysis in March 2016 when the values were as high as 48% different.

There were two instances when results of multiple chemical parameters appeared to be mixed up between two samples and were believed to be reported incorrectly by the laboratory. The data covered samples collected at SMB and the Ocean in both October 2015 and January 2016. After a thorough data review they appeared to have been misreported as a result of changing the analyte order in the spreadsheet tables. The review also considered data consistency with other dates and locations throughout the full dataset. The results were therefore switched for samples labeled SMB with those labeled Ocean in both instances. Most but not all analytes were swapped as the variations in the data reporting were analysis specific. The changed data are highlighted in the data tables and appendices.

There were a few individual data points that appeared to be anomalous (both low and high) when they were evaluated and compared to the entire dataset. An in-depth review of these data did not identify a specific analytical error and were therefore left as is. The inclusion of these data points did not alter the main assessment or conclusions of the dataset.

2.6 MONTHLY MACROALGAE

2.6.1 Sample Collection

Macroalgae biomass and percent cover transects were conducted monthly at up to six sampling locations (Figure 4). Where possible, macroalgae speciation and SAV were qualitatively evaluated. Depending on water depth and visibility either an intertidal or floating macroalgae transect approach along the intertidal mudflat was used. Methodologies used for both were based on methods developed by SCCWRP in their Estuarine Eutrophication Assessment Field Operations Manual (SCCWRP, 2008). Initially each of the six transects (MA1, MA2, MA3, MA4, MA5, and MA6) were laid out parallel to the shoreline roughly 1-m from vegetation edge and a quarter of the way out between the shore and water line. Transect length for each sampling station is provided in Table 10. A 0-m marker was deployed at vegetation edge for each of the 6 stations and was used to find the location from month to month. For those stations (MA2 and MA5) where the total length of the mudflat was 50 m or less a 10 m transect was conducted. Starting in March 2015, transect length for

MA1 was decreased to 10 m due to mudflat erosion. Initially transects were conducted on foot by approaching shore from water via kayak at approximately 2 meters down-stream from the 0-meter marker of each sampling station. Starting in June 2015 through March 2016, conditions allowed for sampling from the kayak. For these sampling events, the kayak was held stationary approximately 1 m off of the vegetation edge at the 0-meter marker and/or at the 30 or 10 m marker depending on sampling station.

Two types of methods were used to collect macroalgae biomass and cover depending on whether or not tidal flats were present or not:

Intertidal method- Macroaglal biomass and cover were collected along a mudflat transect when the shoreline mudflats were exposed during low tide conditions. Percent cover measurements were made using the point intercept method within a 0.5 x 0.5 m PVC quadrat placed onto the mudflat surface at 10 randomly selected distances along the transect tape. Random distances for each survey were predetermined and are provided in Table 11. An example of a quadrat placed on the sediment surface is shown in Figure 9. Percent cover was calculated based on the presence or absence of biomass at each of the 49 intersection points within the quadrat. The type of biomass including macroalgae, submerged aquatic vegetation, and benthic algae (diatoms) was recorded. Percent cover values were based on the average value calculated for the entire transect. Macroalgae biomass measurements were made by collecting algae into a biomass delineator (4 inch x 2 inch depth) placed at the center of five out of ten randomly selected distances on the 0.5 x 0.5 m PVC quadrat (Figure 10). Similar to distances, the five locations selected for biomass collection were randomly selected and predetermined for each survey (Table 11). Using Nitrile gloves, the biomass was removed from within the delineator and placed into a pre-labeled unused Ziploc® bag and kept in the dark on ice in coolers until processed in lab.

Modified Floating Method- A modified floating algae sampling method was used to measure percent cover and biomass along each transect under nearly or completely closed-mouth conditions when mudflats were not present. Percent cover, was made using the point intercept method, however unlike the intertidal method the same four transect points (two on either side of the 0-meter and end transect point, Figure 11) were evaluated for each survey. Figure 12 is an example of a modified floating survey conducted at MA4 in June 2015. Temporary PVC markers were carefully inserted into sediment approximately 1 m from vegetation edge as depicted in Figure 11 and Figure 12, with a quadrat placed at each side of marker. Percent cover was calculated as described above. Macroalgal biomass was sampled by placing the delineator directly onto the mudflat at the approximate center of the quadrat (see Figure 10 for example). Macroalgae was sampled by placing the delineator at a 5-cm depth and cutting it away with scissors. Samples were placed into a pre-labeled Ziploc® bag and kept in the dark and on ice in coolers until processed in lab.

In some instances where floating macroalgae was present the same four point method was used for collection of percent cover however biomass was collected by placing the delineator in the center at a 5-cm depth and cutting it away with scissors. An endcap was placed under the water surface away from the quadrat and bringing up to the surface underneath the delineator to capture the material. Samples were placed into a pre-labeled Ziploc® bag and kept in the dark and on ice in coolers until processed in lab. Figure 12 provides an example of floating macroalgae conditions.

2.6.2 Sample Analysis

Macroalgae biomass samples were processed by scientific staff at SSC Pacific laboratories in accordance with methods provided by SCCWRP for the Bight 2008 Survey as well as the Chesapeake Biological Laboratory who conducted the carbon, nitrogen and phosphorus chemical analysis (Table 9). All samples were transferred to a -4°C refrigerator upon arrival at the laboratory and were processed within 48 hours of collection. Each sample was processed individually. Processing included collection of initial wet weight in pre-weighed weight boats; rinsing of samples to remove excess salts and/or sediment; reweighing of sample to obtain wet weight; shedding of excess water using a salad spinner; and drying samples at 60 °C for a minimum of 24 hours or until fully desiccated. Once the biomass material was fully dried a dry weight was measured for each sample using the same pre-weighed measuring boats. Biomass for each transect was based on the average value from all samples collected along the transect. The final biomass calculation was based on the dry weight (dw) of the algae in grams (g) divided by the area of the 4" delineator of 0.0081 m^2 for final units of g dw/m^2.

Carbon, Nitrogen and Phosphorus Analysis-Once the algae was thoroughly dried and weighed it was ground into fine powder using a mechanical coffee grinder used specifically for this purpose. The ground material was placed into pre-weighed aluminum boats, weighed and transferred into pre-cleaned scintillation vials provided by the laboratory for C, N, P analysis if the sample weight was greater than or equal to 0.5g. Each sample was then labeled with station ID and date and stored at room temperature until shipped to lab for analysis.

Each sample was analyzed for carbon, nitrogen and phosphorus using a CE 440 elemental analyzer. The sample method for each analyte is provided in Table 9, however a full method description can be found on the Chesapeake Biological Laboratory website (http://www.nasl.cbl.umces.edu/methods/WCC.html).

2.6.3 Analysis QA/QC

Macroalgae sampling was conducted in accordance with previously established methods for the Southern California Bight 2008 Regional Marine Monitoring Survey and as outlined in SCCWRP Estuarine Eutrophication Assessment Field Operations Manual, (SCCWRP, 2008). Proper procedures were followed to avoid contamination. Sample collection and processing procedures included; walking and/or kayaking outside of transect zone; using individual pre-cleaned unused

Ziploc® bags and or scintillation vials for holding fresh and or dried, ground biomass; use of pre-cleaned sampling equipment; as well as pre-rinsing all materials with sample water at each sampling location prior to sample collection. Nitrile gloves were worn during both sample collection and sample processing. All samples were stored in the dark on ice and processed within 48 hours of collection under clean laboratory conditions to ensure consistency and less chance of contamination. Dried biomass was kept at room temperature until analysis.

Once submitted to Chesapeake Biological Laboratory data analysis QA/QC consisted of addition of duplicated or spiked samples to10% of all field samples using a standard of known concentration. A quality analysis of data revealed reproducibility within 30% for percent carbon, nitrogen, and phosphorus of submitted algal samples. The QA review also showed evidence of trace amounts of sediment in about 7% of samples. Sample weights could not be corrected for this.

A similar floating macroalgae biomass collection method was utilized under very limited circumstances during SCCWRP's Bight Program (McLaughlin et al., 2012). As a result, a quantitative relationship between these two forms of sampling methods (floating mudflat vs. intertidal mudflats) could not be evaluated. From a qualitative evaluation, and given that some of the macroalgae is not necessarily attached and shifts with the tide, sampling with the floating protocol appeared to yield higher quantities of biomass then what would have been measured on dry mudflats. The quantitative effects on biomass using this protocol versus the intertidal method cannot unquivocably be determined at this time.

Additionally, ~50% of the macroalgae biomass samples contained submerged aquatic vegetation, primarily *Ruppia*. Inclusion of this vegetation in the sample resulted in an overestimate of the biomass concentrations. A review of the data and log book information suggest the overestimate in biomass concentrations would be less than 25%. Where possible, the reported sample weights were corrected to minimize the impact of SAV on the macroalge sample results. Slight spatial bias is expected given that relatively higher amounts of *Ruppia* and other submerged aquatic plants were found higher up in the estuary. While *Ruppia* is not an algae, its presence in large amounts can potentially have an impact on the overall primary production, oxygen generation and respiration of the estuary.

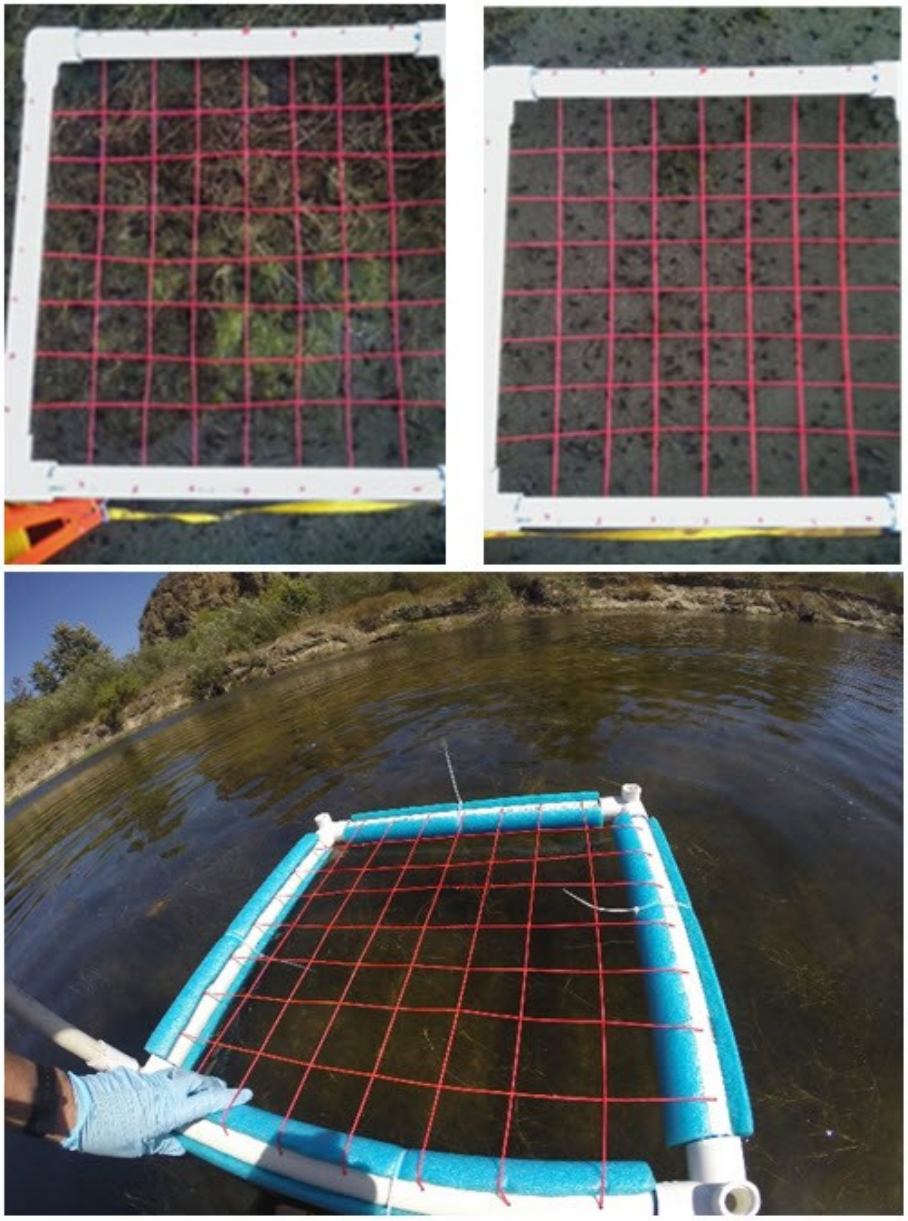

Figure 9. Example photos of quadrat placement. The two top photos from September 2014 survey, show placement of the quadrat on top of a sediment surface with minimal and dense macroalgae present. The bottom photo was taken from June 2015 survey, shows placement of a quadrat above mudflat “floating” conditions.

Figure 10. Example photos of delineator placement. The right bottom photo from September 2014 (MA4) shows placement of the quadrat and delineator on top of a sediment surface that had no macroalgae present. The top right photo from June 2015 (MA3) survey photo shows placement of a delineator during a floating mudflat survey. Left photo, also from June 2015 survey (MA6), shows removal of delineator post sampling in a floating mudflat survey condition.

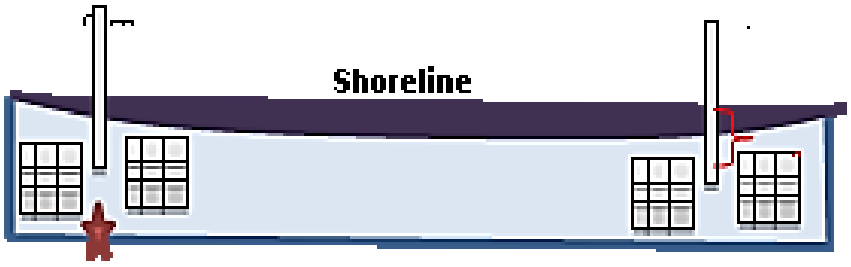

Figure 11. Schematic of modified floating macroalgae transect and placement of quadrats for each survey. (*) Transect length varies from 10 to 30 m depending on total length of mudflat (seeTable 10). The red star indicates co-located sampling of benthic algae and water sampling with 0-m sampling location.

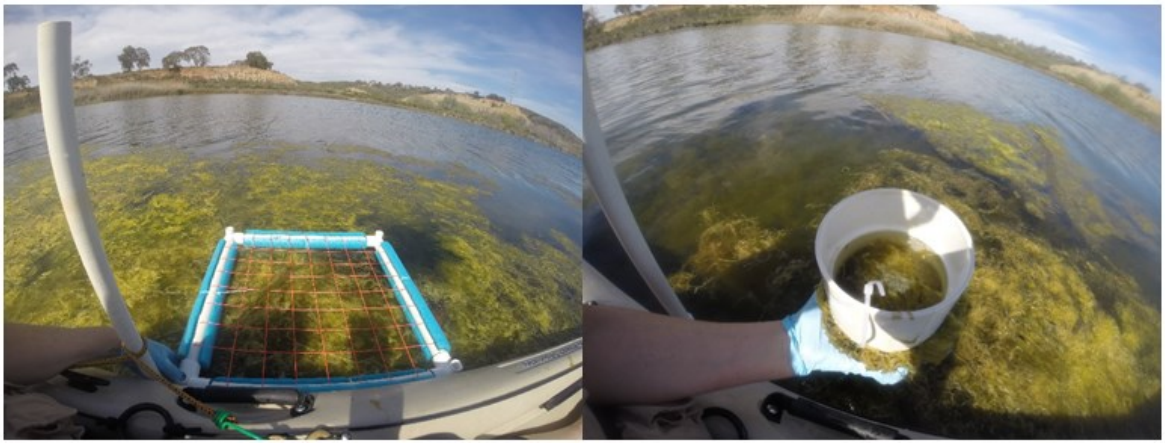

Figure 12. Example photos of biomass survey during floating algae conditions. The left photo illustrates quadrat placement using same four transect point as illustrated in Figure 11. The right photo is a picture of the delineator filled with algae cut away from the surface. Photos were taken at MA4 in October 2015.

The drawn lines are provided to depict the general vicinity of veg edge

2.7 MONTHLY BENTHIC ALGAE

2.7.1 Sample Collection

Benthic algae samples were collected monthly at all six macroalgae locations (MA1, MA2, MA3, MA4, MA5, and MA6) and analyzed for total and active Chl-*a* as well as phaeophytin. Sampling methods were based on methods developed by SCCWRP in their Estuarine Eutrophication Assessment Field Operations Manual, 2008. Excluding MA6, the sampling location was down-slope of the macroalgae 0-meter marker. The MA6 sampling location was approximately 1 m from the MA6 continuous water level sensor location and discrete water sampling site (Section 2.4). All sampling locations were approximately 1 m from vegetation edge in approximately 0.3 m of water. Samples were not collected if water depths were greater than 0.5 meters.

In short, a total of ten 1-cm sediment plugs were collected from the top 1 cm of the sediment column using a cut-off 60 mL syringe sampler in a water depth of approximately 0.3 m. The sediment area was cleared of algae, snails and other debris prior to inserting syringe into the sediment for collection. Extra sediment was removed from the end of the syringe using a spatula prior to expelling each sediment plug into a clean unused Ziploc® bag (Figure 4). All sediment samples were collected by hand wearing nitrile gloves. The samples were kept in the dark and on ice in coolers until processed at the SSC Pacific laboratory for shipment to a commercial laboratory for analysis.

A qualitative assessment of benthic algae percent cover was also included as part of the macroalgae biomass and percent cover quadrat based point intercept survey described previously.

2.7.2 Sample Analysis

Sediment samples were processed by scientific staff at SSC Pacific laboratories in accordance with methods provided by the Chesapeake Biological Laboratory at the University of Maryland Center for Environmental Science, the lab that conducted all of the chemical analyses (Table 9). The 10 aliquot sediment plugs were thoroughly mixed within the Ziploc® bag and approximately 1 mL of sample was transferred to 50 ml sterile conical vial provided by laboratory. The sample volume did not exceed the bottom section of the conical vial. All transfers were made using a pre-cleaned spatula and wearing nitrile gloves. Each sample tube was labeled with a sample ID, date, and the surface area of the sediment plugs and kept frozen at -20°C until they were analyzed at the laboratory.

Each sample was analyzed for total and active Chl-*a* as well as phaeophytin. A brief method for each analyte was described in section 2.5.2 above, however a full method description can be found on the Chesapeake Biological Laboratory website (http://www.nasl.cbl.umces.edu/methods/WCC.html).

2.7.3 Analysis QA/QC

Sample collection and processing procedures included: using pre-cleaned unused Ziploc® bags and or conical vials for holding of sediment sample in field and shipment to laboratory for analysis; pre-cleaned sampling equipment; as well as pre-rinsing all materials with sample water at each sampling location prior to sample collection. Nitrile gloves were worn during both sample collection and sample processing. All samples were stored in the dark on ice and processed within 24 hours of collection under clean laboratory conditions to ensure consistency and less chance of contamination. All processed samples were kept frozen until analysis.

Once submitted to Chesapeake Biological Laboratory data analysis QA/QC consisted of addition of duplicated or spiked samples to10% of all field samples using a standard of known concentration. Both relative and percent recovery of standard addition difference were calculated and included in results. All samples were analyzed within 28 days of receipt of samples.

Figure 14. Benthic algae sampling. The left photo illustrates insertion of the sediment syringe sampler into the mud while pulling up on the syringe plunger. The right photo illustrates sample at 1 cm marker post removal from sediment and use of spatula to cut off excess. Photos taken at MA3 station during October 2014 sampling event.

2.8 MONTHLY MOUTH BERM HEIGHT

2.8.1 Data Collection

Berm height data were collected at the mouth to identify how the mouth opening changed over time and to connect the height measurements to tide and water levels in the estuary. Mouth berm elevation data were collected using a high resolution Global Positioning System (GPS) receiver while walking across the mouth opening when it was open and along transects that crossed or followed along the berm when the mouth was closed. The number and locations of transects and coverage over dry land were determined based on conditions in the field, including the size and shape of the opening, water flow through the mouth, location of the mouth relative to a previous location, and project logistics. Sampling was planned for low or slack tide conditions when the mouth was open to minimize the water depth and amount of flow. In the end, all measurements made during an open-mouth condition always had flowing water.

Between four and six transects were typically made across the mouth when it was open. Elevation data were collected at points along a transect line at roughly 5-m spacing. Distances between transects varied based on conditions but were typically about 40 m apart and ranged between 15 and 70 m apart. Transects across the water were continued onto dry land on both sides of the water course up to ~30 m. Elevations were also commonly collected along the water's edge to outline the shape of the mouth opening (or closure) and obtain another measure of water elevation, and in dry land areas to reoccupy previously measured locations. When closed, measurements of the berm height were made while walking across the berm to find the high spot or along the berm based on visual height and tide line cues. Measurements were collected at between 10 and 100 m apart. Examples of the GPS data collection in the field are shown in Figure 15.

Elevation data were collected with a Trimble GeoExplorer 6000XH GPS equipped with Terrasync version 5.61 cm resolution software. The unit was run with an external Trimble Zephyr2 antenna on a 2-m pole for increased position and elevation accuracy estimated to be 1 and 3 cm, respectively. The unit was set to record data only when the post-processed accuracy was below 20 cm. Raw

position and height data were collected and averaged for a minimum of 20 point measurements (20 seconds) at each location and stored on the unit for subsequent processing.

2.8.2 Data Processing

GPS data were post processed using Trimble Pathfinder Software version 5.8. The data were corrected using the Continuously Operating Reference Site "(CORS), FALLBROOK_CS2004 (P474), CALIFORNIA (ITRF00 (1997)-Derived from IGS08 (NEW))" reference station (www.ngs.noaa.gov/COR**)**. The corrected data were then exported to Microsoft Excel using the WGS84, GEOID12A coordinate system that generates elevation data relative to the NAVD88 vertical datum. These post-processed data were used for berm height evaluation and comparisons to water level in the estuary.

2.8.3 Data QA/QC

The key method to evaluate elevation accuracy and precision was to compare measurements made at two locations in the estuary to previously surveyed-in sites in 2013 to support bathymetry data collection (Kappa, 2013). The first location was a mark placed about midspan on the Stuart Mesa Bridge. The second location was the top of a PVC pipe placed just east of the northbound I-5 Bridge and that was used to house a levelogger® sensor for water level measurements. The bridge site position and elevation was measured each visit with the Trimble Geo6000XH unit with the external 2-m antenna.

A comparison of measured position and elevations each month and the surveyed-in location are shown in Table 12. Evident from this dataset was that the elevation was noticeably lower in November 2014, and January, April, October, November, and December 2015 than it was on the other14 occasions. The jump in elevation was also observed at two other markers that were checked on either end of the bridge. The elevation on these occasions was lower by as much as 80 cm. This issue was discussed with Trimble technicians but was never resolved. Therefore, a correction was applied to the mouth survey elevation data for those dates when there was a clear jump in the elevation measured at the bridge. The correction was based on the difference between the measured elevation and the average value calculated for the other remaining elevations. The average value excluding the low months was 5.882 m ± 1.4% relative standard deviation (RSD). The average measured elevation value was 1.0 cm different than the surveyed in elevation of 5.883 m. The precision value of 1.4% translates in ± 8.2 cm. The average measured position was 14.4 cm from the surveyed in position. Though mouth data were corrected for the vertical differences described above, no correction was applied to the horizontal data.

Elevation data of the water surface in the estuary were occasionally collected both at the mouth and in the estuary when it was closed. These data, including those that had been corrected as described above, were compared to water level data collected at the I-5 Bridge. The differences averaged 9.6 cm indicating that the elevations corrections were appropriate.

Table 12. Position and elevation values measured monthly at a surveyed-in location on the Stuart Mesa Bridge. The values were used to assess GPS elevation measurement accuracy and precision. Gray cells were not included in the accuracy or precision calculations. Mouth data were adjusted by the difference in elevation on those dates and the average value calculated for all other dates. The average measured value of 5.882 m was virtually the same as the surveyed-in elevation value of 5.883 m.

Figure 15. Examples of mouth berm elevation survey data collection using a Trimble GPS with 2-m external antenna. Measurements were made while crossing the mouth when open and on dry land locations around the mouth area when closed. Two photos on the left show the estuary in a closed-mouth condition.

2.9 AXIAL SPATIAL MAPPING

2.9.1 Data Collection

Spatial mapping of estuary water quality was conducted by towing the Troll multiparameter sensor package alongside a kayak on an east-west zigzag transect from the Stuart Mesa Bridge to the estuary mouth similar to the track shown in (Figure 5). Mapping was conducted during closed-mouth conditions on 18 May 2015 and again on 14 June 2016. The axial mapping was extended further upstream in the estuary in 2016 as the water course was cleared of vegetation at that time. The Water depth, conductivity, salinity, temperature, dissolved oxygen, and pH were collected every 10 seconds at a nominal depth of 30 cm. Position data were collected using a Differential Global Positioning System (DGPS) unit measuring at 1-s intervals. The along track spatial resolution of the water quality data collection was approximately 5 m. A photo of the kayak and sampling setup is shown in Figure 16.

Discrete water samples were collected in the ocean and at 10 stations along the zigzag transect inside the closed estuary. These samples were collected, processed, and analyzed for nutrients, TSS,

and Chl-a similarly to the monthly discrete water sampling effort described above in Section 2.5.2. Axial Station 4 was at the I-5 Bridge while Axial Station 7 was collected at the Stuart Mesa Bridge. The kayak was stopped at each station during sample collection. Sample positions for both surveys are shown in Table 13 and Table 14.

2.9.2 Data Processing and QA/QC

Instrument calibrations were conducted before the survey using standard methods. The sensor and DGPS data were downloaded to a computer after the survey and time matched to form a single dataset. The data were reviewed graphically to ensure consistency and to remove extraneous data that occurred when the instrument was pulled from the water when it caught up on algae and when going ashore at the two bridges to swap out sample bottles. The discrete water sampling and analysis quality was conducted as previously described for the monthly discrete water sampling and analysis (Section 2.5.2).

Figure 16. Kayak setup for axial survey at the closed-mouth of the estuary in May 2015. Buoys off the side of the kayak were used to float the Troll sensor unit. The GPS antenna is visible at the stern.

2.10 BATHYMETRY

2.10.1 Data Collection

Bathymetry data were collected on 19 and 20 May 2015. The data were collected using a Teledyne Oceanscience Z-Boat® 1800 remote control hydrographic survey boat with integrated Hemisphere A101™ GPS and Ceepulse 100™ 20 kHz echosounder. The remote control vessel was manually operated using joy stick controls from a nearby kayak or shoreline (Figure 17). Data were collected along transects that were run primarily in the cross-channel direction though some locations warranted collecting data along the estuary longitudinal axis. The nominal spacing between transects was ~10- m but varied as a result of conducting the survey manually using visual cues. The system

collected bottom depth data at a 6-Hz data rate and GPS data at 5-Hz. All data were stored on-board the Z-Boat®'s data management system for post-processing.

2.10.2 Data Processing and QA/QC

The bathymetry data processing began with a data download from the Z-Boat® data system to a comma separated file that was further processed with a combination of Microsoft Excel® or MATLAB®. The GPS and bottom depth data were time-matched into a single datafile containing a total of 32,817 x, y, and bottom depth records. These data were evaluated for outliers, errors, and overlaps, particularly when the Z-boat® was too shallow for a good reading (~0.3 m), got stuck on the shoreline or sandbar, or when the Z-Boat® was brought to shore for battery changes or other operational tasks. Best professional judgement was used to make these corrections. The bottom depths in this dataset were then corrected for boat transducer depth (3.9 cm), measured (1528) versus the default sound velocity setting of 1500 m/s (1.87%), and then converted into the NAVD 88 vertical datum using the water surface elevation measured at the I-5 Bridge. This datum was then converted to mean sea level (MSL) using a 0.774 m offset between the two (NAVD88 +0.774 m = MSL). The final dataset is provided in the appendices.

The data were also gridded and contoured using Golden Graphics Surfer® software to create final graphical data representations. The gridding was conducted using a Krigging method with settings of: no anisotropy, a search radius of 100 m, a grid resolution of 2x2 m, and one pass of a weighted distance filter. A blanking boundary file based on the outline of the estuary from Google Earth. A few additional editing was conducted on the final grid using grid editing in Surfer® to eliminate artifacts of the gridding process. A comparable dataset was collected and processed in similar fashion in 2013 and compared to this dataset in the results section. The 2013 data are also provided in the appendices.

Figure 17. Bathymetric survey work in upper estuary. The yellow vessel is an Ocean sciences Z1800 remote control boat collecting position and water depth data. The vessel was remotely controlled by a joystick operated in the nearby kayak.

3. RESULTS

3.1 CONTINUOUS WATER QUALITY MONITORING

Water quality data were continuously collected from the I-5 Bridge and SMB buoys for 639 days and 634 days, respectively except for the three days in December 2014 when the buoys were removed in anticipation of high storm flows. The maximum number of measurements collected at 15-min intervals was 60,856 at I-5 and 61,208 at SMB for a total of 122,064 records. The five variables measured included depth, temperature, specific conductivity, dissolved oxygen, and pH. Salinity and dissolved oxygen equilibrium saturation were derived from the combination of temperature, specific conductivity, dissolved oxygen, and depth sensor data. The pH sensor at the I-5 Bridge buoy was broken during a calibration/cleaning process resulting in no data collection between 23 August and 17 September 2015 (2729 records). As described previously, up to 30% of the DO and conductivity data were recalculated when biofouling affected the results. The number and percent of data records collected and adjusted are shown in Table 15.

The final dataset used for evaluation and generating statistics was based on a condition when all parameter data for both buoys were simultaneously available, with minor exceptions. This dataset consisted of 60, 478 records from each buoy as shown in Table 16. Data eliminated from the combined dataset included the first week of data collected at SMB before the I-5 buoy came on line and when the buoys were undergoing calibration checks. The minor exceptions included timeframes when pH data were missing only at the I-5 Bridge buoy when the sensor was broken (pH: n = 57,787) and when the DO data could not be corrected at the SMB buoy (DO: n = 59,557). The final combined dataset represents 98.5% of the total records collected.

The overall dataset showed relatively low variability with RSD values ranging from ~3% to 34%. The largest variability was observed for dissolved oxygen and temperature. Dissolved oxygen values ranged between 0 and 14.1 mg/L and averaged 6.3 mg/L while temperature (RSD = 23%) ranged from 8.6 to 31.6 °C and averaged 20.7 °C. Salinity ranged from near 0 to 41.4 psu, averaged 34.4 psu, and had an overall RSD of 8.5%. The least variable data were pH that ranged between 7.4 and 8.8 and averaged 8.1. With the exception of pH, seasonal variations were considerably higher than the average spatial differences observed between the I-5 and SMB monitoring sites, which were less than 5% for all variables. The spatial differences and temporal variations of pH were roughly the same.

The range and variability in values was reasonably similar to those measured in 2011 near the I-5 Bridge by SSC Pacific (Katz and Rivera, 2012) with the following notable exceptions:

1. Average temperatures during this recent monitoring period were 1.8 °C warmer
2. Average salinity values were higher by 13.8 psu and were less variable by a factor of seven
3. Average dissolved oxygen values were less by 1.9 mg/L and by 10% in saturation level

The observed levels and variation of these physiochemical water quality parameters were driven by daily and seasonal changes in solar insolation/heating, the relatively low freshwater inflow during the monitoring period, and most importantly, the amount of tidal exchange when the mouth was open or lack of exchange when it was closed. The effect of mouth closure on the data is shown in Table 17. Average temperature, salinity, and pH were 22%, 10%, and 2% higher, respectively during closed conditions, while dissolved oxygen concentrations were lower by 19%. However, the differences were not statistically significant at $\alpha = 95\%$.

The primary changes observed in estuarine water temperatures were related to strong seasonal changes in solar insolation and heating (Figure 18). The seasonal changes in water temperatures mirrored daily high air temperatures measured at the Vista, CA monitoring station. Maximum temperatures at the I-5 Bridge of 30 °C were reached in September 2015 when the mouth was closed. In comparison, maximum temperatures reached only 27 °C when the mouth was open in September 2014 even though air temperatures were comparable. The overall warmer temperatures observed during the recent monitoring period were a result of having a closed-mouthed condition that eliminated tidal exchange with cooler ocean water. The closed-mouth condition also resulted in smaller daily temperature variations of ~2 °C throughout 2015 compared to 8 to 10 °C variations observed under open-mouth conditions in 2011.

Like temperature, salinity values showed strong seasonal trends. Salinity increased to maximum values over 41psu between the middle of August and early October 2015 under a closed-mouth condition (Figure 19). The maximum levels resulted from evaporation exceeding precipitation and freshwater inflow, particularly during the closed condition. Salinity levels were significantly lowered throughout the estuary during rain events, and typically rebounded back between a few days up to a few weeks depending on the storm size. Daily variations were only a few psu throughout the entire period, even when the mouth was open. The overall higher average salinity and its limited variability compared to past years reflect both the limited exchange with the ocean even when it was open and the relatively low rainfall totals. Rainfall averaged 7.4" over the past four years versus 13.3" the previous four years (Figure 20). The resultant surface freshwater input over the past five years dropped from an annual average of 53 cfs to 15 cfs (Figure 21). Although surface freshwater inflow was limited, salinity was on average 1 psu lower at the upstream SMB station than at I-5. This reflects the freshwater flow coming in from the watershed from either surface or groundwater flow and was consistent with the axial transect data described later in the report (Section 3.7).

Additional changes in salinity occurred during closed-mouth conditions when especially high tides and/or or waves overtopped the berm as shown in (Figure 22). The plot shows a drop in salinity at SMB in response to ~0.5, 0.4 and 0.2 in rain events that occurred on the 5th, 6th and 7th of March 2015, followed by an increase in salinity that occurred on the 8th when the berm was overtopped during both high tide and high wave conditions. Examples of these types of changes occurred throughout the monitoring period.

Dissolved oxygen concentrations in the estuary also showed a strong seasonal trend that was opposite in direction to the trends in temperature and salinity. The trend is shown in a plot of the full dataset in Figure 23 as well as in Figure 24 that plots the data as a daily average. Daily average concentrations were 7.1 and 6.5 mg/L at the I-5 and SMB bridges, respectively for roughly the first six months of the monitoring period when the mouth was open. Daily maxima at this time reached up to 12 mg/L with daily minima mostly above 5 mg/L at I-5 and above 4 mg/L at SMB. The daily variations were a result of primary production by phytoplankton, macroalgae, benthic algae, and submerged aquatic vegetation that generates oxygen during daylight hours and respiration in both the water column and sediments, that depletes oxygen primarily at night (Figure 25).The average daily values trended down through the summer closed-mouth condition to levels of about 5.0 and 3.1 at I-5 and SMB, respectively. At this time dissolved oxygen maxima of 14 mg/L were observed at both locations. Daily average concentrations increased into winter to levels of about 8 mg/L when the mouth reopened in February before trending downward again to about 6 mg/L into summer.

The observed daily and seasonal trends have been observed previously (Katz and Rivera, 2012; McLaughlin et al., 2013) in the estuary but appeared to reach lower daily average levels under a fully closed-mouth condition due to a lack of flow and tidal exchange with the ocean. The impact of a closed-mouth condition on the data can be seen in the Figure 26 that illustrates the cumulative

frequency of dissolved oxygen values at both bridges, for the entire dataset, and for data measured during only open and only closed conditions. This plot, as well as the tabulated percentages (Table 18) indicate a significantly lower percentage of the data fall below the 5 mg/L San Diego Basin Plan objective, during open-mouth conditions. Percentages ranged from 2.8 to 14.9% at I-5 and SMB, respectively for open-mouth conditions and from 26 to 35.4%, respectively, for closed conditions. These data reflect the general spatial differences with overall lower dissolved oxygen concentrations that occurred at the upstream SMB station relative to downstream station at I-5. Overall levels were below the 5 mg/L threshold 21.1% of the time, 9.3% for open-mouth and 28.2% closed-mouth conditions. These data are indicative of presence of higher levels of algae and oxygen demand in the estuary during summer conditions. Approximately 1 mg/L of the reduction (on average) resulted from higher salinities and temperatures that physically lower the amount of oxygen the water can hold in equilibrium with the atmosphere.

Table 15. Summary of continuous water quality sensor data records acquired at the two bridge locations. The summary includes the total number and percentage of possible data records collected as well as the number of data records and percentage that were recalculated as described in the methods section.

Closed	26.6%	35.4%	28.2%

3.2 CONTINUOUS WATER LEVEL

The complete water level dataset collected for the I-5 Bridge is shown in Figure 27 along with ocean tides measured at La Jolla, CA (Station 9410230). Both levels were referenced NAVD88.The data clearly show three periods when the mouth was closed between 9 and 17 February 2015, 31 March through 23 December 2015, and again 26 February 2016 through the remainder of monitoring in June 2016.

Water levels in the ocean showed typical tidal variations for the region, with spring tides ranging from about -25 to +200 cm (NAVD88), and neap tides ranging from about +50 to +125 cm (NAVD88). In contrast, the variations in the estuary during open conditions were lower by about 50%. During the same period, minimum levels in the estuary generally did not drop below about +100 cm (NAVD88). Maximum levels were similar to ocean levels during periods when the entrance to the estuary was open (September 2014 through April 2015 and 15 December 2015 through March 2016). During periods when the mouth was closed, the variations in the estuary were generally very small. Variations during those periods were characterized by non-tidal fluctuations showing sharp rises on the order of about 10–50 cm within a period of a single day, generally followed by slow declines on the order of 5–10 cm per month.

A closer view of the data during a period when the mouth was open is shown for the week of 21 October 2014 in Figure 28. At this resolution, additional factors become apparent. The water levels in the estuary tend to lag the tides in the ocean by about 1–2 hours at high tide, and by as much as 3–5 hours at low tide. Because of this lag, the high tide peaks in the estuary tend to be somewhat smaller than the peaks in the ocean, as the water level gradient tends to reverse before the estuary can fully fill. The dampening on the outflow from the estuary was very pronounced and is clearly the result of flow limitation through the mouth. In particular, the berm height at the mouth (and the cross sectional area) tend to limit the extent to which the estuary can interact with the tides in the ocean. The dampened outflow and lack of a low tide condition resulted in limited or no intertidal areas on which to sample macroalgae biomass using the intertidal method, as described previously (Section 2.6.1).

A closer view of the data during a period when the mouth was transitioning from open to closed is shown for the 2-week period starting on 25 March 2015 in Figure 29. From this figure, we can see that the berm height must have started to increase on or about the 27th and by the 31st had reached a height above the high tide level such that no tidal fluctuations are observed in the estuary after that date (until it re-opened many months later). This represents a growth in the berm height of at least 60 cm in a relatively short period of time.

As discussed previously, there can be leakage of ocean water into the estuary even when the mouth is closed as a result of either extreme high tides such as those observed in Figure 30 and/or as a result of rainfall and wave overtopping with significant wave heights such as those observed in Figure 31. In both figures the ocean and estuary water levels were overlain with significant wave height data measured at the Oceanside buoy (National Data Buoy Center Station 46224, http://www.ndbc.noaa.gov/station history.php?station=46224). In these instances water levels in the estuary increased as much as 50 cm above the maximum tide height in the ocean because water flowed into the estuary without an equivalent process to drain it.

Figure 32 shows the 2-week period starting 21 December 2015 when the mouth of the estuary reopened. The reopening occurred relatively quickly, initiating on the 24th and transitioning to a partially open condition with a berm height on the order of about 100 cm (NAVD88) by the following day. This figure shows that the reopening event occurred during the peak spring tides. The spring tides in this case corresponded with a high wave condition that was also preceded by a modest sized rain event of about 25 mm between the 21st and 23rd that resulted in a negligible increase in river discharge or level (USGS gage 11046000). The reopening thus appeared to correspond to wave action at the beach berm rather than breakthrough by river flow.

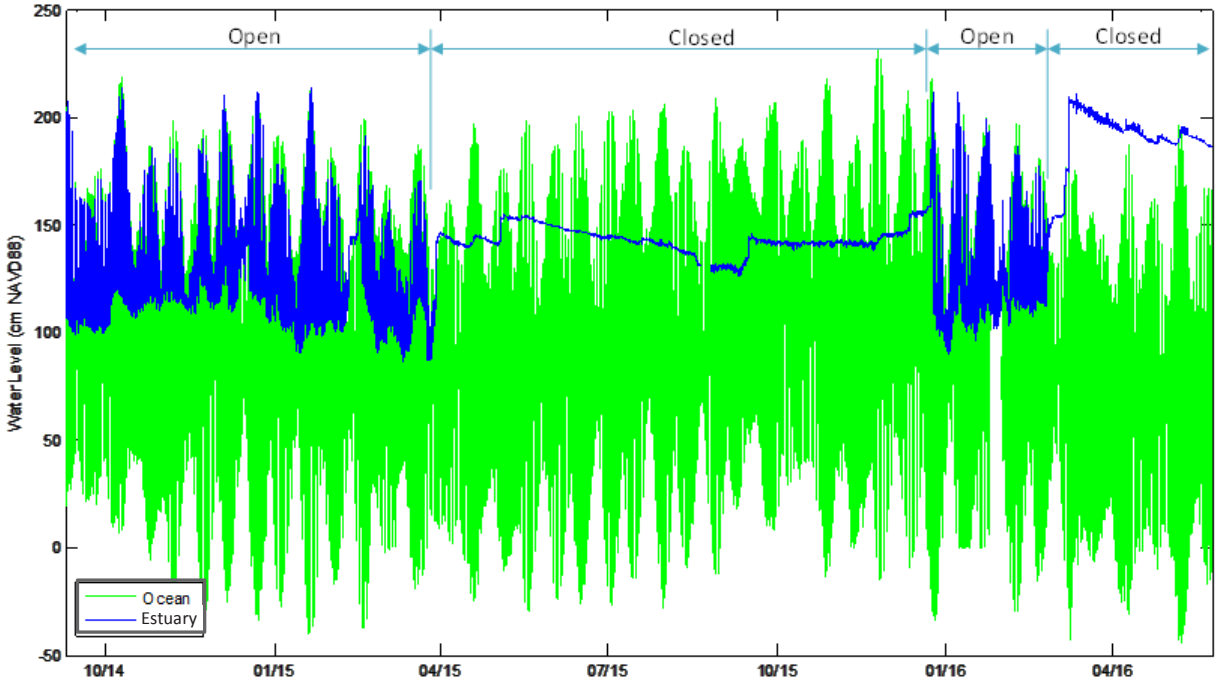

Figure 27. Water level measured at the I-5 Bridge and NOAA predicted tides for La Jolla, CA. Water level changes show that the mouth was closed between 9 and 17 February 2015, 31 March through 23 December 2015, and again 26 February 2016 for the remainder of monitoring through June 2016.

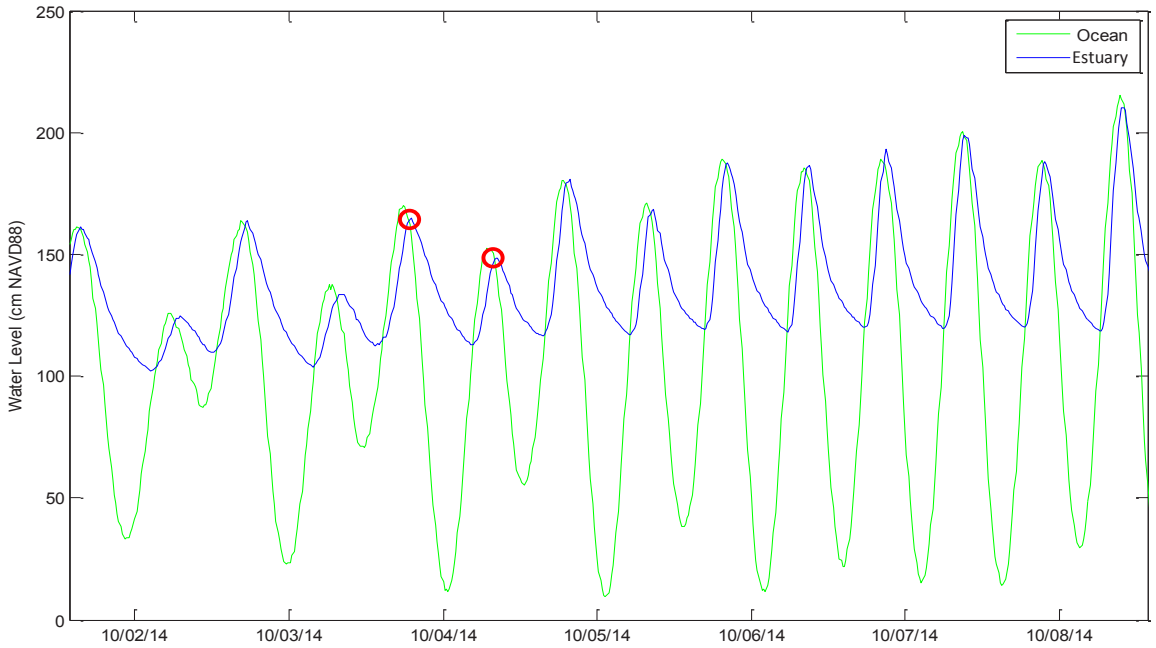

Figure 28. Water levels in the ocean and estuary during a mouth-open period. Red circles indicate water level crossing times.

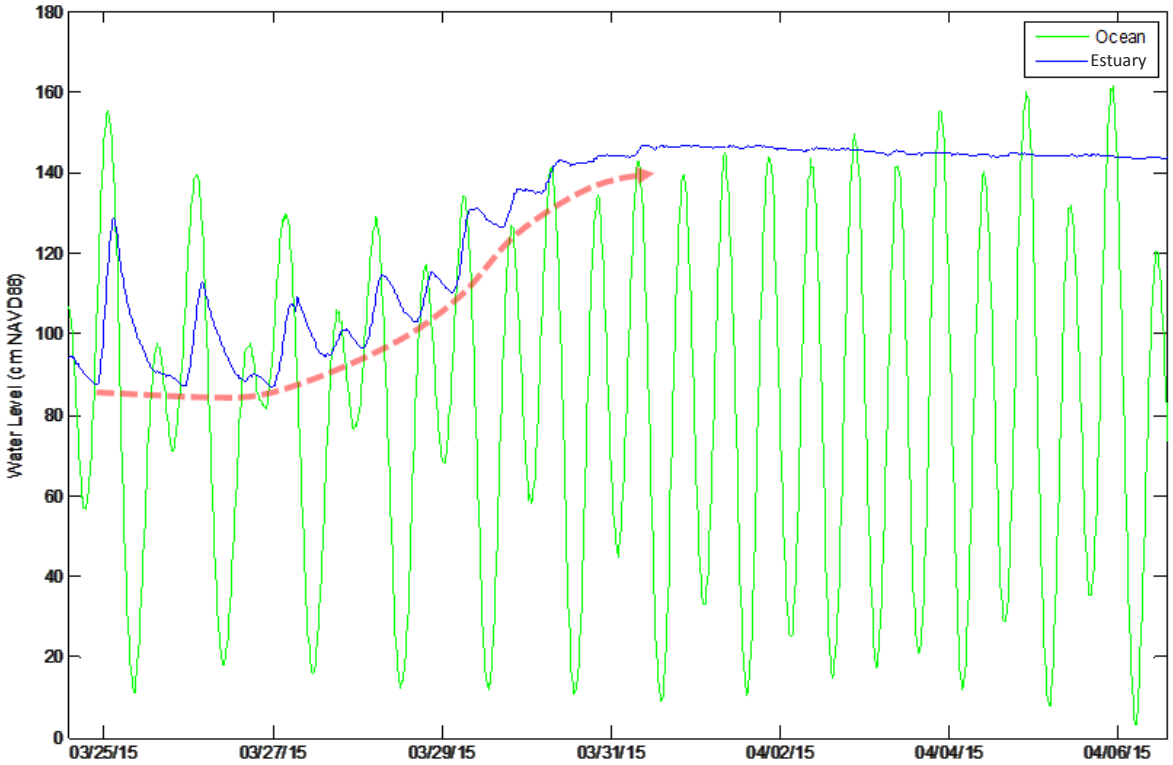

Figure 29. Water levels in the ocean and estuary during a mouth-closing event. The red arrow suggests the trend in berm height at the mouth.

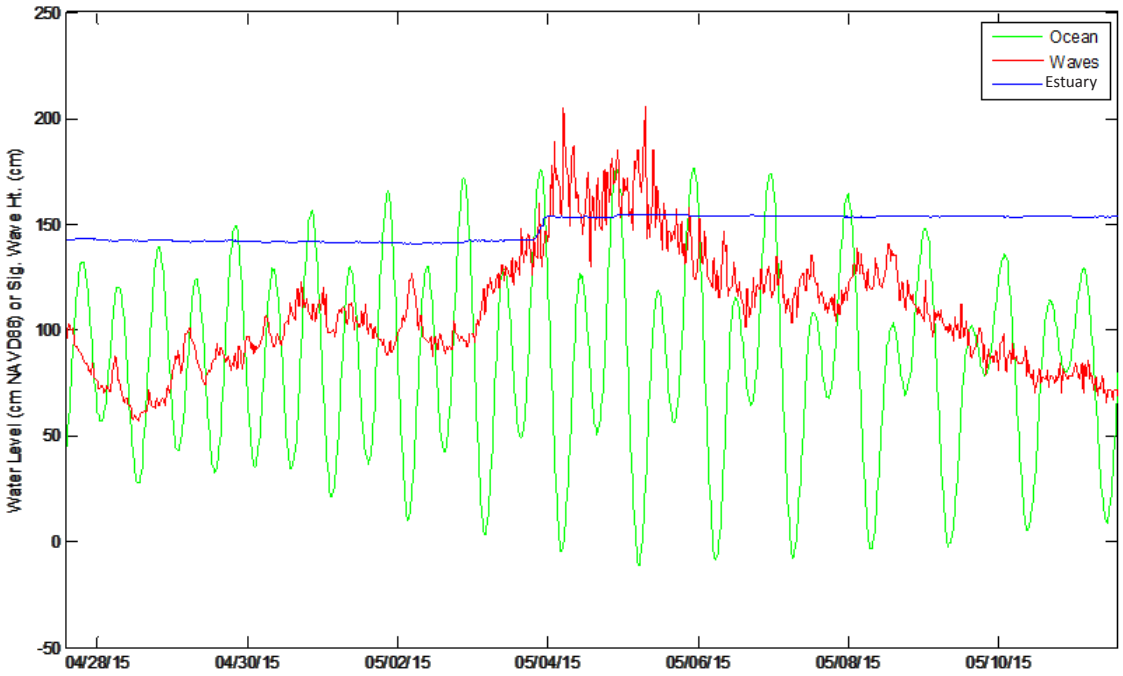

Figure 30. Water levels in the ocean and estuary along with significant wave heights observed during a closed-mouth. Overtopping of the berm by a combination of tides and waves resulted in an increase in estuary water level.

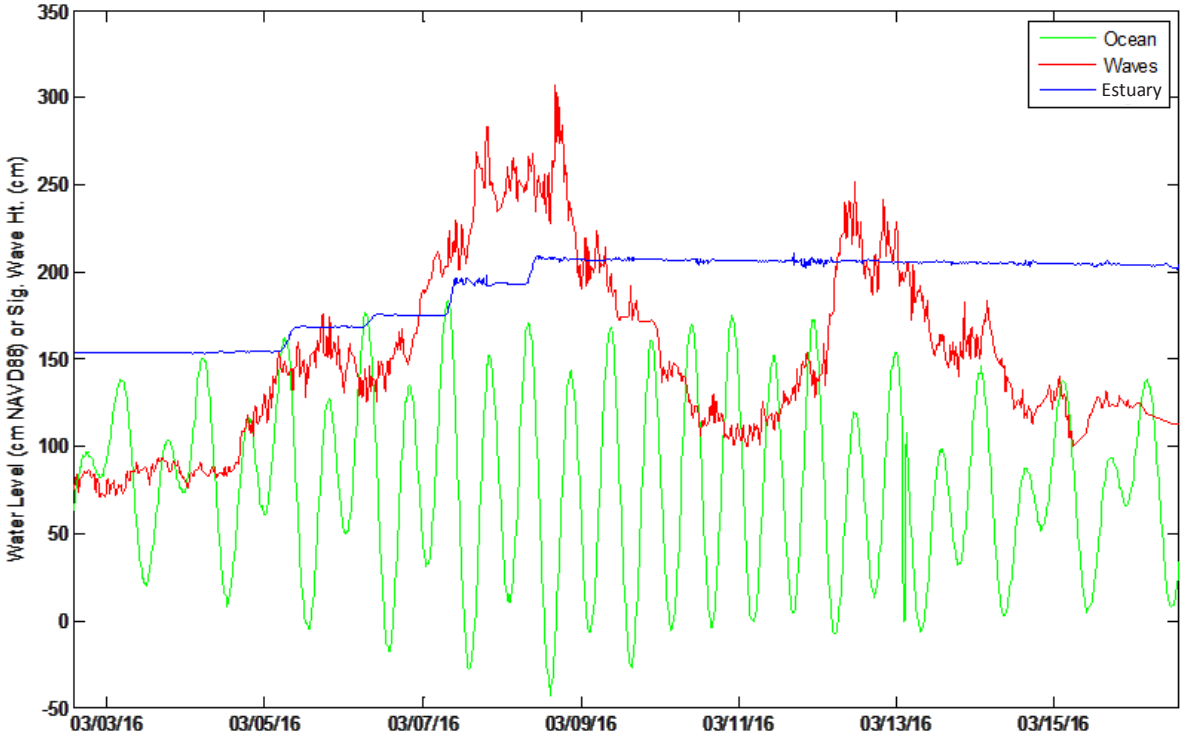

Figure 31. Water levels in the ocean and estuary along with significant wave heights observed during a closed-mouth. Rainfall along with overtopping of the berm by waves resulted in an increase in estuary water level.

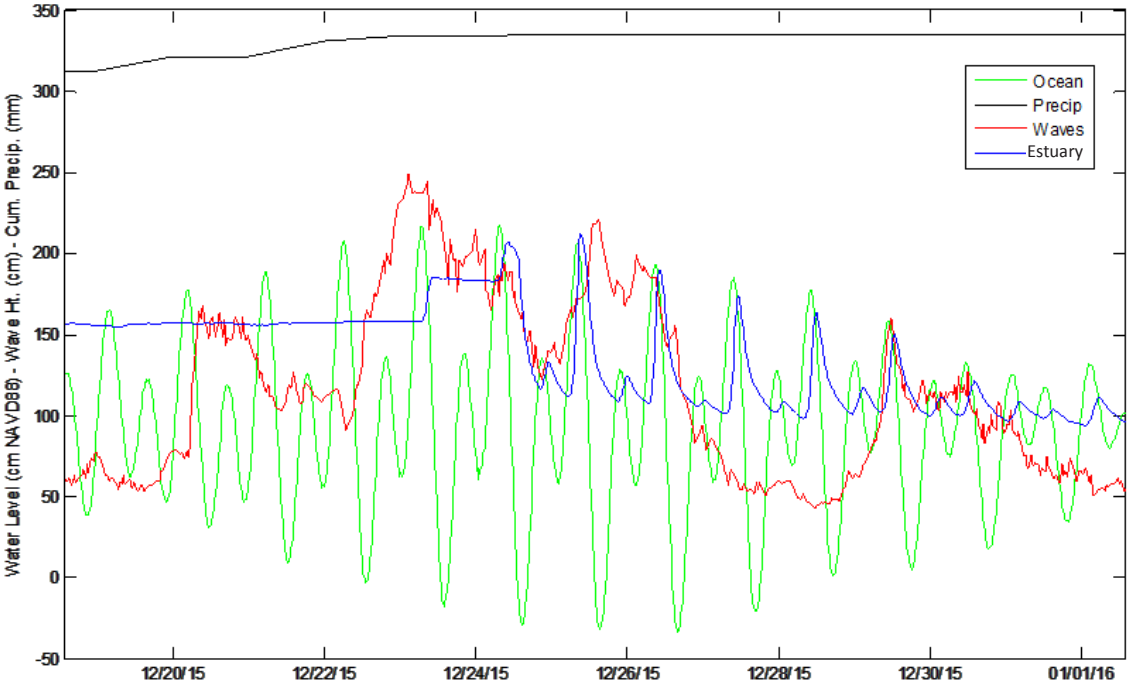

Figure 32. Water levels in the ocean and estuary along with significant wave heights and cumulative precipitation during the mouth-opening event in December 2015.

3.3 MONTHLY WATER QUALITY MONITORING

Discrete water samples were collected monthly at six stations, five in the estuary including the two bridges at three of the six macroalgae (MA) stations, and one in the ocean (OC). All samples were analyzed for a suite of nutrients, Chl-*a*, and total suspended solids. The data for the 138 samples are shown in Table 19. The dataset in the table also includes discrete water samples collected during the two axial surveys (May 2015 and June 2016),which also included samples collected at the two bridges, the ocean, and at an additional nine stations along the zig-zag transect described previously in Section 2.9. One additional sample collected from Lake O'Neil in September 2015 is included at the bottom of the table. Excluding the Lake O'Neil sample, all data are shown in chronological order of the date collected.

A statistical summary of the discrete water sample data are shown in Table 20. Total nitrogen ranged from 0.14 to 2.1 mg/L and averaged 0.66 mg/L. Total phosphorous ranged from 0.03 to 1.1 mg/L and averaged 0.29 mg/L. The vast majority (80%) of the total nitrogen data were below the Basin Plan objective of 1 mg/L. In contrast, only 30% of total phosphorous data were below the Plan objective of 0.1 mg/L. Total suspended solids ranged from 2.4 to 103 mg/L and averaged 32 mg/L. Total phytoplankton Chl-*a* ranged from 0.5 to an exceptionally high value of 109 µg/L measured at MA6 in September 2015. The average value was 7.9 µg/L. Samples collected in the ocean were lower in concentration for all parameters than those measured in the estuary except for NO3+NO2-N. A few ocean samples had TSS concentrations above those measured in the estuary, though it is believed that these represent samples that were likely elevated as a result of resuspended material in the surf zone.

On average, both nitrogen (79%) and phosphorous (84%) were found primarily as the dissolved fraction. The inorganic fraction of nitrogen was relatively low, averaging ~10%, while the inorganic fraction of phosphorous averaged ~68%. Though the particulate phase of nitrogen and phosphorous

were relatively low, they were reasonably well correlated to particulate carbon ($R^2 = 0.96$, 0.51, respectively). The average PC:PN:PP ratio was 25:5:1. Total Chl-*a* was primarily (77%) composed of active Chl-*a*.

The data showed considerable variability over space and time with RSD values ranging between 60% for DN to 182% for phaeophytin (Table 20). Most of the variability in the data was a result of temporal changes, though spatial variation along the longitudinal axis of the estuary was evident as well. The data showed strong seasonal trends in estuarine nutrient concentrations that corresponded to trends in temperature and salinity, the amount of surface freshwater inflow as a result of rainfall, and most importantly to the open or closed condition of the mouth. The temporal trends in total nitrogen and phosphorous at the I-5 and SMB bridges (Figure 33 and Figure 34) showed a general pattern of gradual but increasing concentrations from spring into summer and fall, followed by a drop off from winter into spring. Similar trends were observed for nearly all nutrient parameters and totals suspended solids at all locations.

The temporal pattern showed a pronounced increase in nutrients and chlorophyll-*a* during the summer of 2015 when the estuary mouth was closed to exchange with the ocean (Figure 35). The increase in nutrient concentrations was consistent with the gradual rise in water temperature and salinity of the estuary during the period, which promote diagenesis, or the remineralization of nutrients from decomposing organic matter, particularly phosphorous (Jordan, Cornwell, Boynton, and Anderson; 2008). The peak in September was potentially enhanced by storm water loading from a reasonably large storm the week prior to field sampling (Figure 36). In the absence of tidal exchange, these nutrient sources resulted in concentrations well above those that were observed in the estuary during significantly larger rain/discharge events in winter when the mouth was open.

The relationship of total nitrogen to total phosphorous was highly correlated ($R^2 = 0.79$) indicating they have similar sources, or that they are regulated by similar processes in the estuary (Figure 37). The same was true of the relationship between the dissolved fraction of each nutrient, though less so for the particulate phase. Three samples deviated from this general relationship, suggesting they had different sources. These data points represent one sample collected from Lake O'Neill in September 2015 when the lake was being drained and two samples collected shortly after relatively large rain events in January and April 2016, from MA6 and SMB, respectively. While the data in January and April appear to be connected to the timing of a storm water source, they were not consistent with any other data collected from the estuary at that time. Thus, their source cannot be further elucidated.

Spatial trends were evident in the monthly monitoring as well as on the axial transects. Figure 38 shows the distribution of time-averaged TN, TP, and Total Chl-*a* for each station measured over the monitoring period. All three plots show a similar pattern of increasing concentrations from the ocean to the top of the estuary. Average oceanic concentrations of TN, TP, and phytoplankton Chl-*a* were all considerably lower than estuarine values. Concentrations in the estuary increased roughly 20% for TN and TP from MA1 to MA6. On average, total Chl-*a* increased ~15% between MA1 and SMB but jumped up by a factor of ~3.5 at MA6, driven by a few exceptionally high observations >60 µg/L. These spatial variations compare to temporal variations measured by RSD for TN, TP, and Tot Chl-*a*, at 60%, 90%, and 100%, , respectively and were comparable to most of the other measured water quality parameters. These results indicate that temporal changes were generally more variable than the observed spatial variations, with the exception of phytoplankton Chl-*a*.

Total nitrogen, phosphorous, and phytoplankton Chl-*a* concentrations collected during the axial data surveys in May 2015 and June 2016 are shown in Figure 39, both under closed-mouth conditions. Oceanic concentrations of TN and TP were considerably lower than the estuarine values though Total Chl-*a* were comparable. The distributions showed a slight decrease of ~15 to 20% in

TN values from the region west of the I-5 Bridge to the region east of the bridge on both occasions. Total phosphorous concentrations were relatively consistent throughout the estuary on both occasions. Total Chl-*a* concentrations were patchy and did not show a consistent spatial trend. In all instances, concentrations were higher in June 2016 than in May 2015.

A review of spatial trends from all discrete sampling locations during open or closed conditions showed a consistent pattern in which nutrients decreased up the estuary during open conditions but were relatively flat or decreased up the estuary under closed conditions such as during the axial surveys (Figure 40). The results are consistent with a watershed source during open and generally wetter conditions and with observed higher productivity levels up the estuary during closed-mouth conditions as is described in the next section.

Table 19. Discrete water monitoring results. Grayed out cells were corrected from the laboratory report as described in the methods. Blue colored cells show TDN data that had low reproducibility in sample replicate analyses as described in the methods. NA = Not analyzed. One sample result collected from Lake O'Neill (LO) is shown at the very bottom of the table.

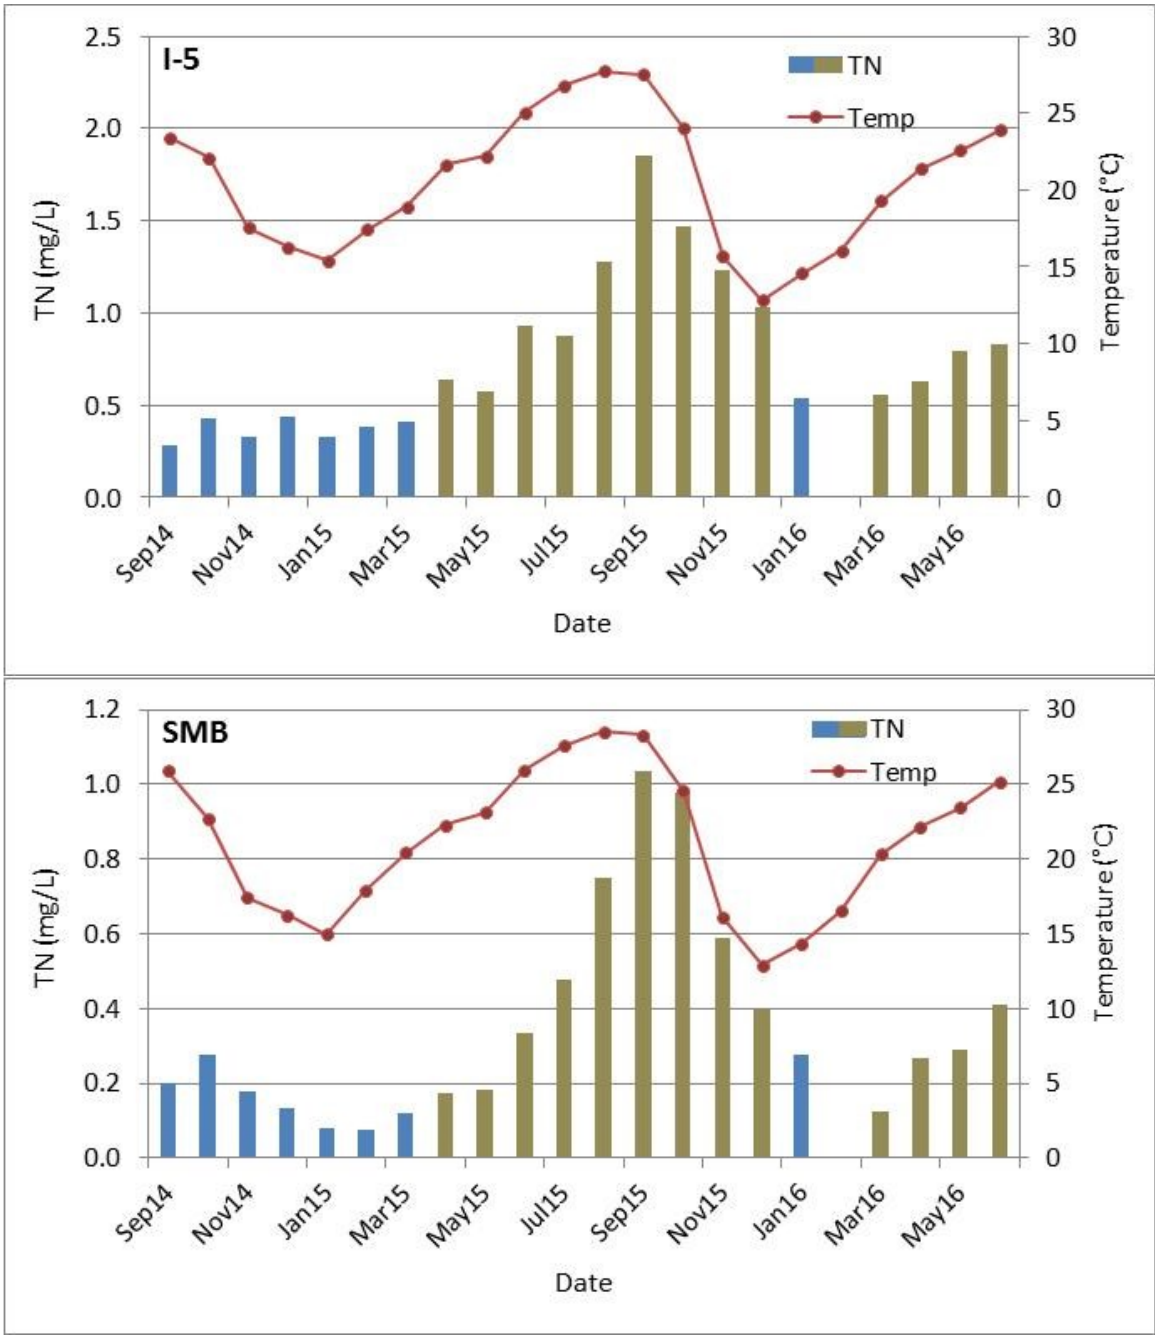

Figure 33. Average monthly total nitrogen measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature at each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016.

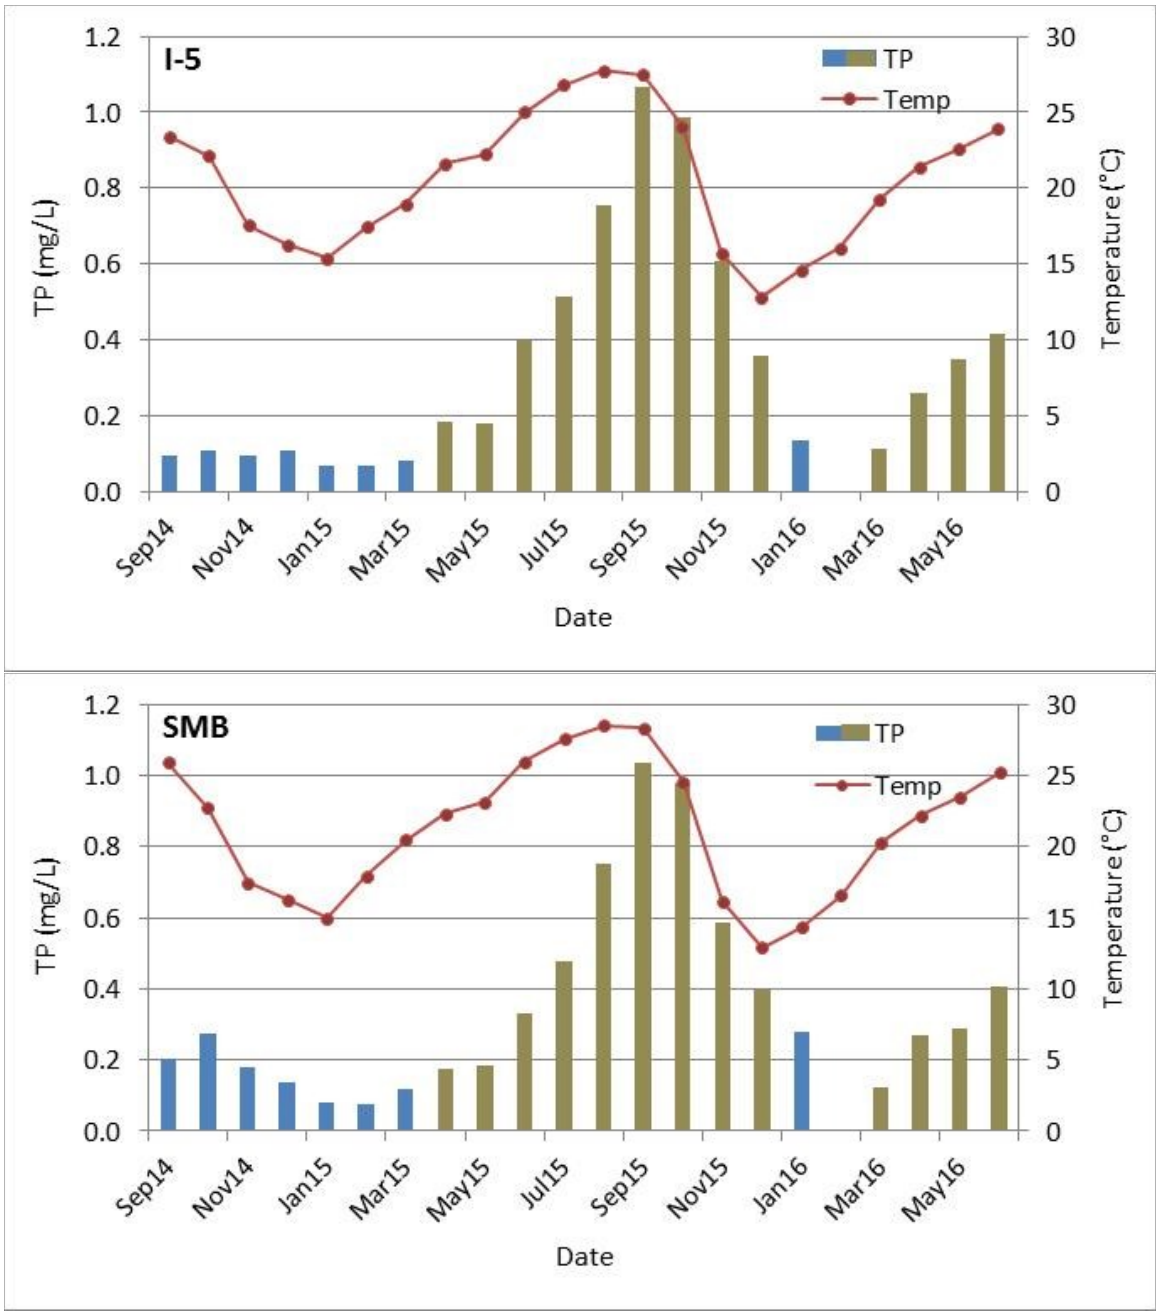

Figure 34. Average monthly total phosphorous measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature for each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016.

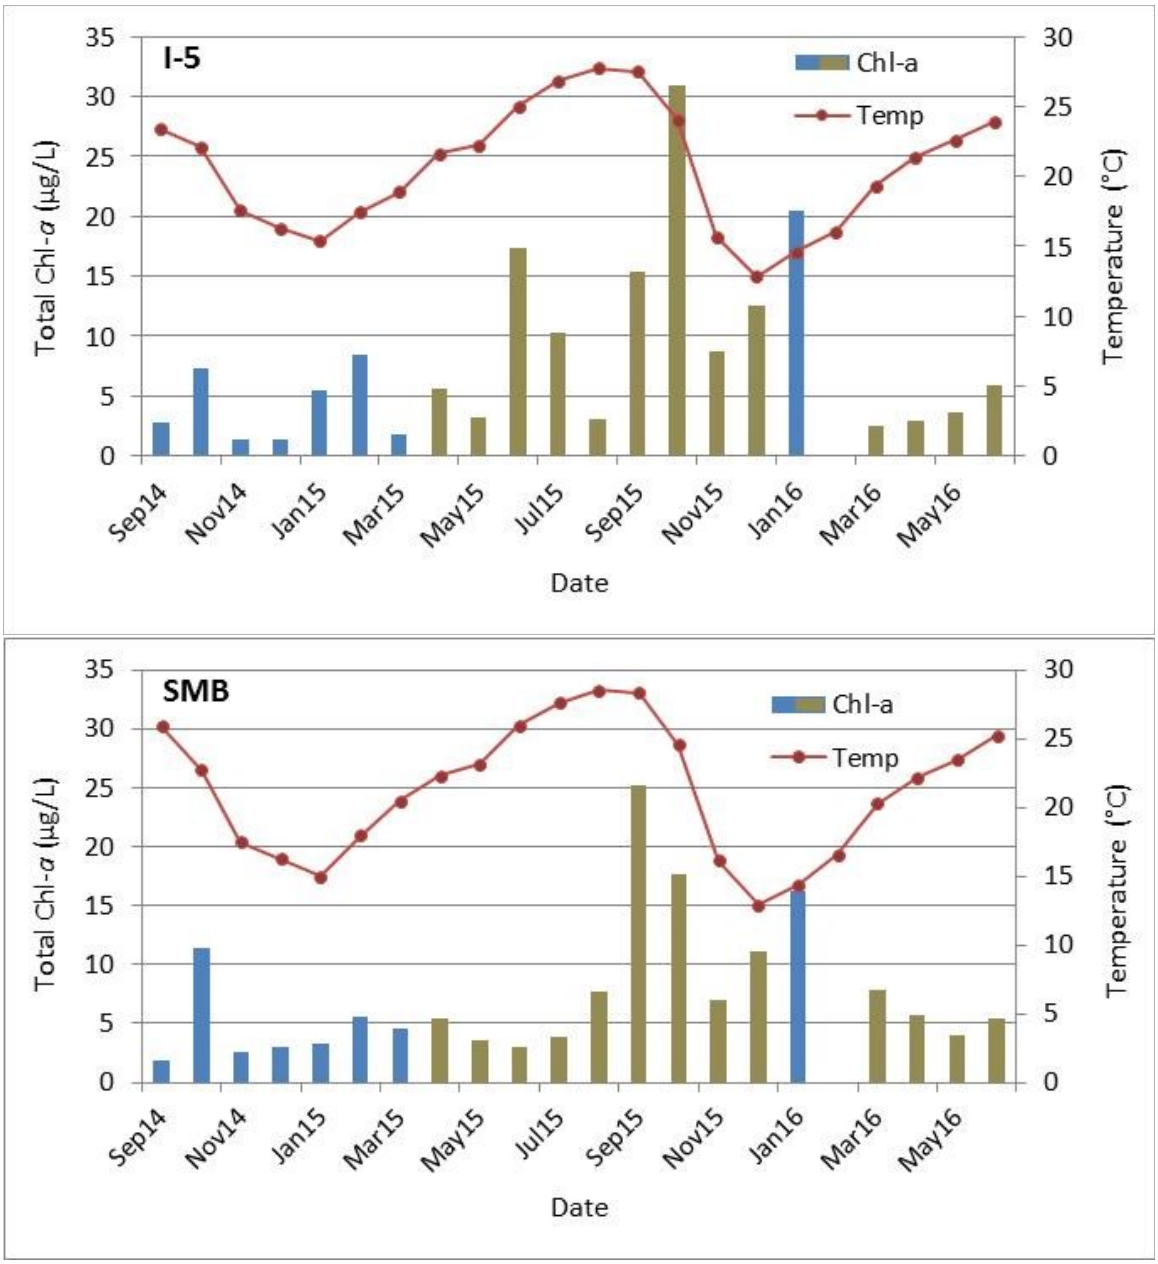

Figure 35. Average monthly total Chl-*a* measured in discrete water samples at the I-5 (top) and SMB (bottom) bridges. Average monthly water temperature for each bridge is plotted as well (red line). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. No samples were collected in February 2016.

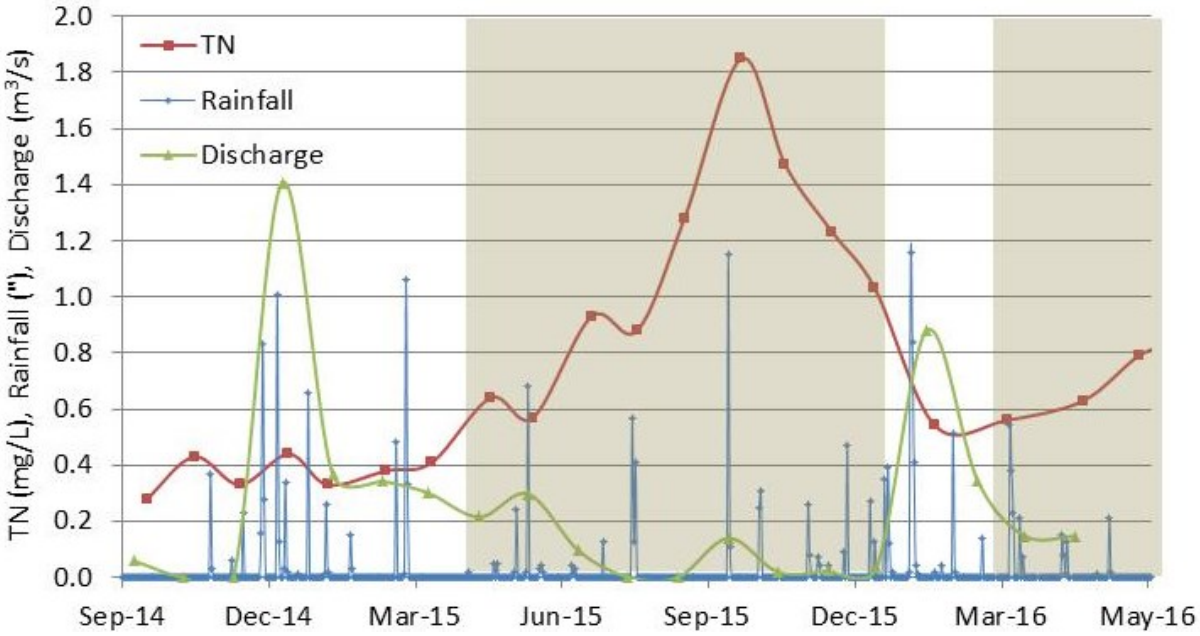

Figure 36. Average monthly total nitrogen, rainfall, and monthly average discharge measured at the Ysidora gage. The brown highlighted region of the plot spans the timeframes of closed-mouth conditions.

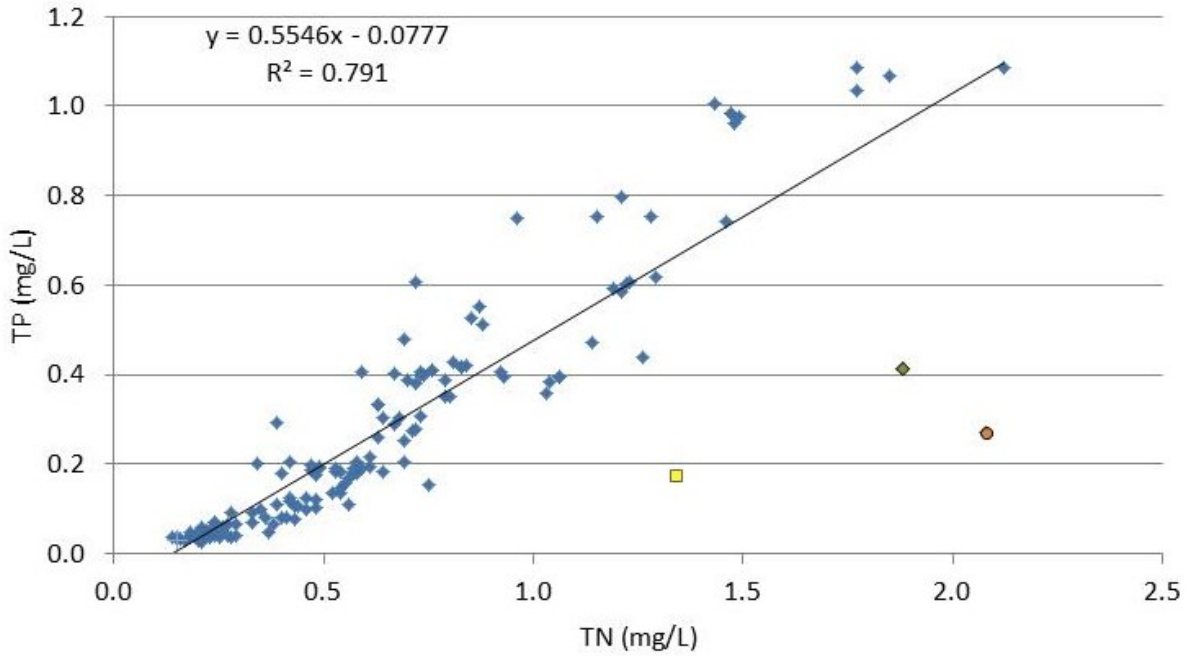

Figure 37. Total nitrogen vs. total phosphorous for all discrete water sample data collected during the 21-month monitoring period. Three points falling off the linear regression line include a sample from Lake O'Neill (yellow square), from MA6 in January 2016 (green diamond), and from SMB in April 2016 (orange circle). The Lake O'Neill sample was not included in the regression.

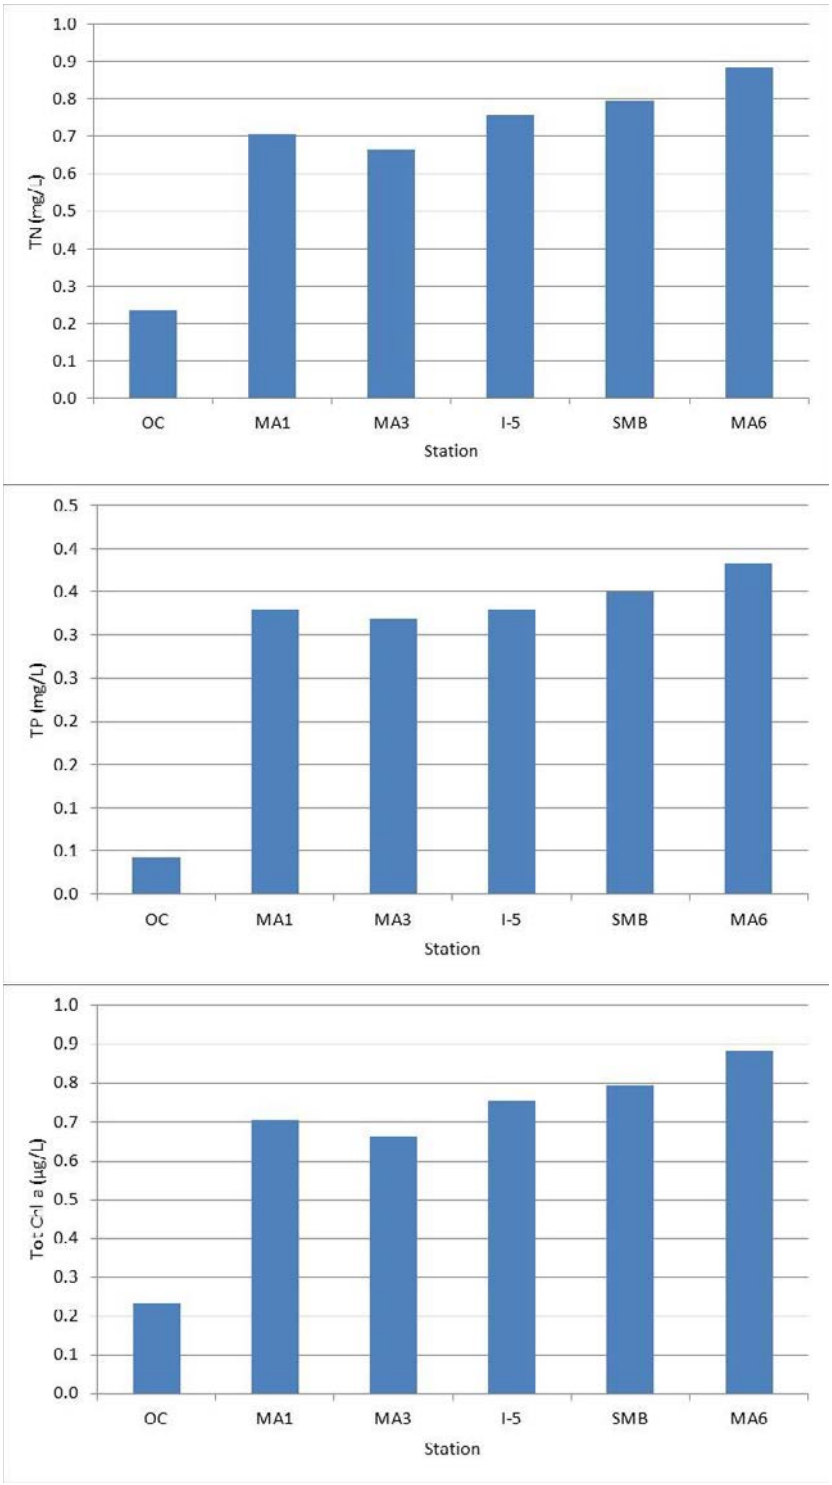

Figure 38. Average total nitrogen (top), phosphorous (middle), and Chl-*a* (bottom) measured throughout the 21-month period at the six monthly discrete water monitoring stations.

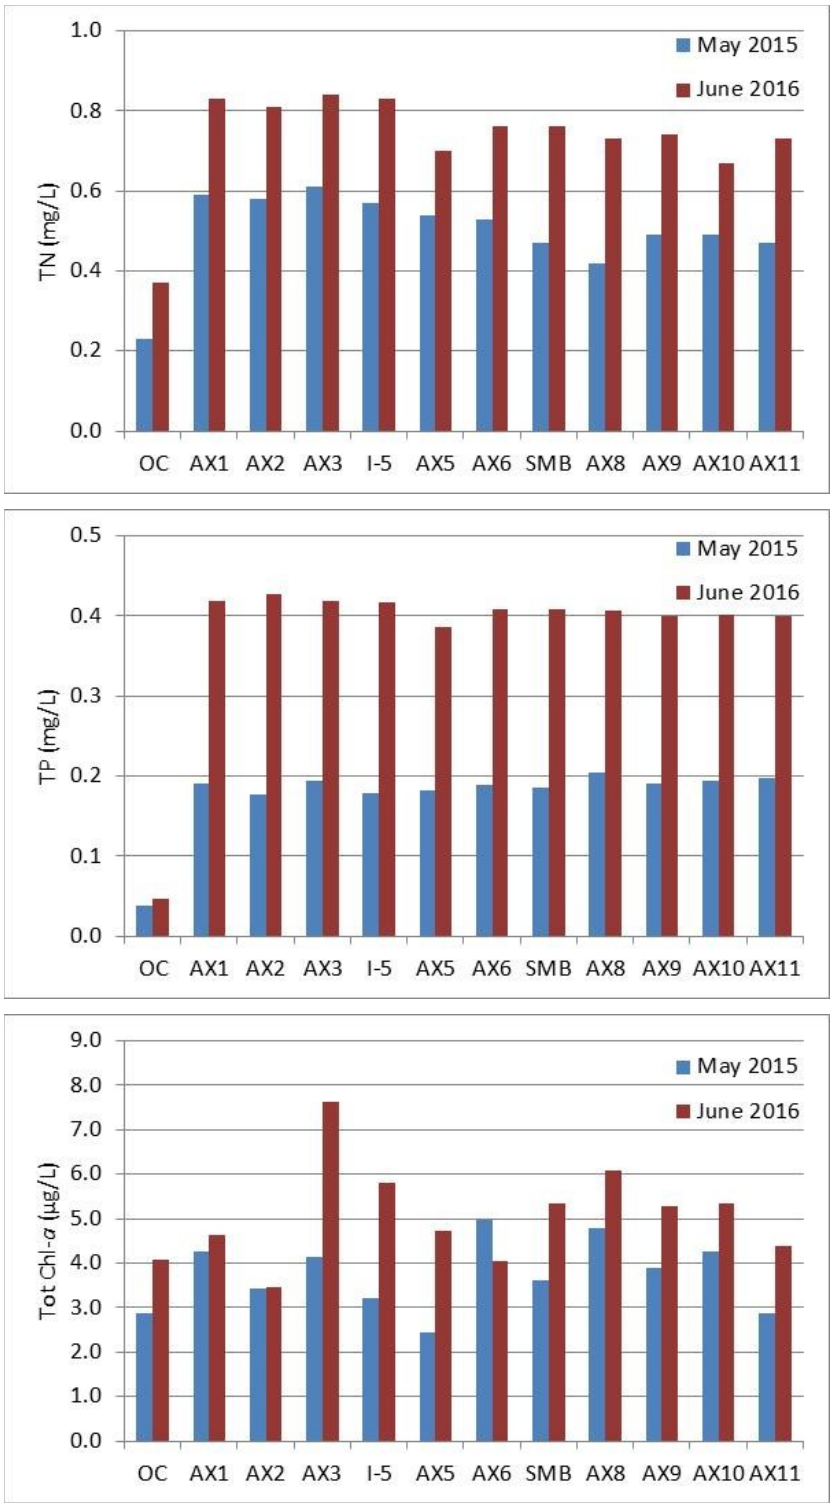

Figure 39. Total nitrogen (top), phosphorous (middle), and Chl-*a* (bottom) concentrations measured in samples taken during on the axial mapping surveys in May 2015 and June 2016. The mouth was closed during both events.

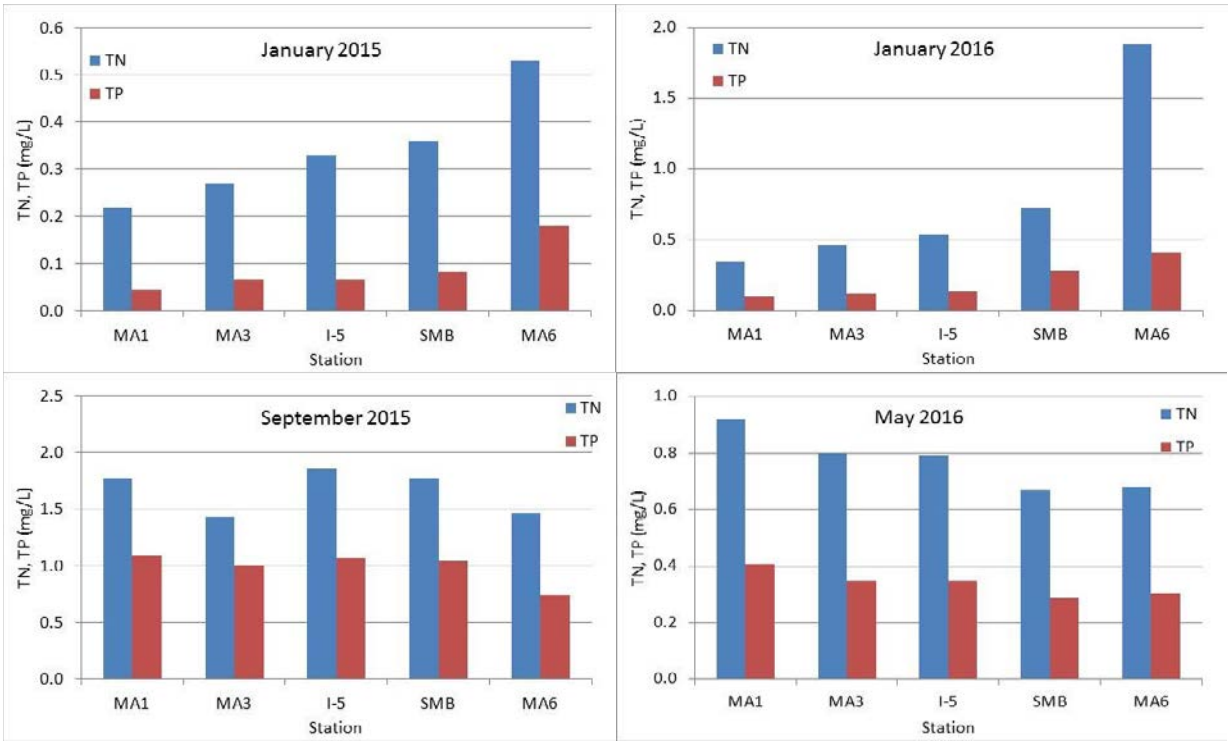

Figure 40. Spatial distribution of TN and TP during two open-mouth conditions in January 2015 and 2016 (top plots) and during two closed-mouth conditions in September 2015 and May 2016 (bottom plots).

3.4 MONTHLY MACROALGAE

3.4.1 Macroalgal Biomass

Results of the monthly macroalgal biomass collection and analyses are summarized in Table 21. All data are provided in the appendices. The table shows a total of 84 sample results with at least two samples collected during each field survey. Sampling at all 6 stations only occurred for six of the 18 monthly visits. Not all of the stations were sampled on all 18 visits. The main reason for not sampling a station was related to water levels exceeding allowable depths as outlined in the sampling protocol (Section 3.6.1), a result of the nearly or completely closed-mouth conditions throughout much of monitoring period. With the exception of the first survey conducted in September of 2014, all samples were collected using the modified floating algae protocol, referred to here after as just floating algae protocol (see Section 2.6).

As described briefly in Section 2, the floating algae protocol was used even though its exact quantitative relationship with measurements made with the standard intertidal method are not known. The decision to use this method of collection was based on the fact that, excluding the September 2014 survey, intertidal mudflats were consistently covered with water which would have excluded the collection of biomasson nearly every occasion. Also described briefly in the methods section, SAV, primarily *Ruppia*, *spp.* was not separated out in the biomass measurement for approximately 50% of the samples collected resulting in a potential overestimation of the macroalgal biomass values. A review of the data indicated that the overestimation would be less than 25% of the total biomass if SAV were present in the sample. In addition, submerged aquatic plants were generally more prevalent in the upper estuary resulting in a potential spatial bias. The following results should be considered within the context of these issues.

The summary statistics for the dataset are shown in Table 22. Concentrations of macroalgal biomass ranged from 0 to 894 g dw/m^2 and averaged 208 g dw/m^2 with an overall RSD of 116%. Examples of low and high macroalgal biomass levels are shown in Figure 41. Estuary-wide averages ranged from 27 g dw/m^2 in January 2016 to 510 g dw/m^2 in September 2015 during the summer closed-mouth condition. Variability in biomass was greatest at MA1 (RSD = 253%) closest to the mouth and the least at the most upstream station MA6 (RSD = 57%).

The average value of all station data collected during each survey, values representing estuary-wide averages, are plotted in Figure 42. The temporal pattern in macroalgal biomass concentrations was patchy. The monthly averaged data showed peaks in October/November 2014 during open conditions, in February through April 2015 during open into closed conditions, and a maximum in September 2015 during closed conditions. Low values of biomass were coincident with an open-mouth and the relatively high runoff discharge conditions in late December 2014 and January 2016 (Figure 43), presumably as a result of scouring. The peak value observed in September 2015 was coincident with the general late summer increase in average monthly water temperatures and salinity (Figure 42) and the build-up of nutrients during a closed-mouth condition (Figure 44). The summer closed-mouth period with relatively high algae, was potentially stimulated by the build-up of nutrients derived from diagenesis, storm runoff discharge, and watershed groundwater as described in the previous section. The macroalgal biomass peaks observed in November/December 2014 and again in February/April 2015 could not be tied to a set of specific conditions though the mouth closed for a brief one week period in February (Figure 45) and was followed by very warm sunny conditions, that together with some rainfall in the same period, could help to explain the bloom. Based on anecdotal visual observations, the estuary appeared to be in an algal bloom condition during the timeframe.

Macroalgal biomass showed a strong spatial gradient with concentrations increasing up the estuary when averaged over the entire monitoring period at each station. The average station values ranged from 16 g dw/m^2 at MA2 to 416 g dw/m^2 at MA6 (Figure 46). The spatial differences were consistent with generally increasing temperatures, nutrients, and phytoplankton Chl-*a* averaged through the monitoring period (Figure 38). While there was a general increase in macroalgal biomass up the estuary, there was considerable month to month variability of the peak value at each station location. Station MA6 had the highest macroalgal biomass on 44% of the visits but the mid-estuary stations of MA4 and MA5 had peak biomass levels 39% and 11% of the time, respectively. Thus, peak biomass levels were found at one of the three upper estuary stations 94% of the time. The inability to collect macroalgae data at all locations on each visit limits the ability to evaluate this further.

Macroalgae collected during the surveys was evaluated for its carbon (C), nitrogen (N), and phosphorous (P) content. The ratios of these elements to each other (C:N:P) averaged over the entire dataset was 101:15.8:0.22 (or 459:72:1). These compare to the ratios of 106:16:1 for phytoplankton based on Redfield (1934) and more closely to the ratios of 550:30:1 for macroalgae and plants based on the Atkinson and Smith ratio as shown in McLaughlin et al., (2013). There was a slight increase in particulate phosphorous up the estuary but there was no spatial trend in either particulate carbon or nitrogen. The percentage of phosphorous content in the macroalgae was considerably higher in February 2015, which coincided with increased macroalgae. The average spatial relationship of biomass with nutrients was positively correlated with $R^2 = 0.6$ for both TN and TP.

3.4.2 Macroalgal Percent Cover

Macroalgal percent cover data are summarized in Table 23 and plotted as estuary-wide averages in Figure 47 and as station averages in Figure 48. Individual station measurements of macroalgal percent cover ranged from 0 to 100% and averaged 37% overall for the monitoring period. Estuary-

wide averages of percent cover ranged from 15% to 74% with the lowest values observed during open-mouth periods and higher flows and the highest values observed in the summer months during closed-mouth periods. A bloom was also observed in February 2015 during a closed-mouth condition. Macroalgae percent cover like biomass had a strong spatial gradient with values increasing for the upstream monitoring stations (Figure 48). Station averaged values ranged from 7% at MA2 to 69% at MA6. Peak cover values were observed at MA6 on 67% of surveys with 94% of the peak values found at the upper three station locations. Though there was a lack of correlation of biomass with cover on an estuary-wide basis, they were highly correlated when evaluating the data on a station-averaged basis (Figure 49). Biomass concentrations of > 300 g dw/m^2 were associated with cover values of ~50% or greater. This relationship suggests that percent cover may be a useful surrogate on those occasions when algal biomass cannot be collected and measured.

3.4.3 Macroalgae and Submerged Aquatic Vegetation Speciation

Monthly surveys for macroalgae biomass and percent cover included an evaluation of types of macroalgae and SAV present to the lowest classification feasible. So as to compare with prior studies, a more generalized classification such as red (*Rhodophyta spp.*), green (filamentous green algae), yellow (*Xanthophyta spp.*), or blue green algae (*Cyanophyta spp.*) was used. Table 24 provides a summary of the predominant types of macroalgae and SAV found throughout the study.

Macroalgae – The estuary as a whole was rather heterogeneous from a species diversity perspective having a variety of algal species present with changing abundance over time. This observation was consistent with what has been reported previously (McLaughlin, Sutula, Cable, and Fong, 2013) and is also reflected in the calculated Shannon-Weiner diversity and Evenness indices of 1.90 and 0.77 respectively. Results of macroalgae species observations by station are summarized in Table 25. The table shows a total of 489 single species observations, across six sampling locations for 12 macroalgae species classifications. The total number of individual sampling station observations ranged from 29 to 142 with the greatest number of single species observations at MA4 followed by MA6. The most common species observed were two green algae, *Cladophora spp*. (CLD), and *Enteromorpha spp*. (ENT), as well as one red species, *Gracilaria spp*. (GRA). The least common species observed were Ce*ramium spp*. and two unidentified species from the *Cyanophyta* (blue green algae) and *Xanthophyta* (yellow hair algae) family. Figure 50 provides a summary of the percentage of total observations for each class of macroalgae listed in Table 24.

In general, the temporal pattern of species composition or diversity was variable but appeared to peak relative to richness (number of classes observed) in the winter season (November and December 2015 as well as January and February 2015) as shown in Table 26 and Figure 51 The lowest degree of diversity was observed in late spring and early summer (June of 2015 and May of 2016). A few of the more consistently observed species such as ENT, CLD, and GRA appeared to have some clear seasonal peaks. The species *CLD*, for example, peaked in late fall (October–November 2015) and early spring (March, 2015), reaching up to 67% average monthly observations (Figure 52). This type of seasonal pattern is consistent with what has been reported previously for this species (Bellis and McLarty, 1967; Wong, Clark, Kirby, and Kosciuw, 1978) and has been generally attributed to shifts in temperature (Graham, Auer, Canale, and Hoffmann, 1982). On the other hand, the species GRA peaked in fall (September and October 2014) and winter (January 2015) with 41%, 38%, and 32% average monthly observations (Table 24), respectively. Overall, three green species of macroalgae, ENT, CLD, and *Ulva spp.*, had the highest percentage of observations across the estuary in March 2015, October-November 2015, and March 2016 (Table 26, Figure 52). Some of the more rare species such as unidentified yellow-green hair algae from the family *Xanophyta* and blue green algae from the family *Cyanophyta* were observed in the winter season.

In general, diversity was higher east of the I-5 Bridge. The calculated Shannon-Weiner diversity (H) and Evenness indices (E) for each of the six monitoring stations were generally higher upstream, ranging between 1.42 and 1.95 and 0.57 and -0.78, respectively. The total number of observations for each recorded macroalgae classification at each of the 6 monitoring stations, as well as their relative (H) and (E) values are summarized in Table 25. The most common species observed across all monitoring stations were CLD, ENT, GRA with average station observations of 6.3%, 3.2%, and 3% respectively. CLD and GRA were also the two species with the highest percentage of total observations at any one station with CLD and GRA, both 10% at MA4 and CLD (9.2%) and GRA (6.3%) at MA6 (Figure 52). The two stations with the greatest degree of species richness (i.e. number of classes observed) were MA3 and MA4, with a total of 9 and 11 classes of macroalgae recorded over the course of the monitoring period. Station MA2 had the lowest degree of richness observed with only five different macroalgae classes recorded throughout the monitoring period Figure 52.

Average species diversity was well correlated with percent cover ($R^2 = 0.62$, Figure 53 and Figure 54). Similar trends have been reported by other researchers (Kraufvelin et al., 2010 and Fatemi et al., 2012). A weak negative association was observed with biomass, benthic Chl-*a* and salinity ($R^2 = 0.16$, $R^2 = 0.29$, $R = 0.22$, respectively, Figure 53). While these associations have not been noted in prior studies, McLaughlin et al., (2012) observed a negative association to benthic Chl-*a* and macroalgae biomass especially in estuaries with semi-diurnal or diurnal tides. This may suggest a species diversity association as well, as Prathep, Wichachucherd, and Thongroy, (2007) and Kraufvelin et al., (2010) reported that a more stable community with higher species diversity was typically associated with calmer waters. The association of macroalgae speciation to other analyzed parameters was limited or inconclusive when evaluated on a temporal basis.

Generalized species classification- Comparing species diversity on both a spatial and temporal scale to prior studies for the estuary was difficult due to limitations in either the type of information collected such as in the Bight 2008 program (McLaughlin, Sutula, Cable, and Fong, 2013) or in the number of observations (Katz, and Rivera, 2012). For example, the 2008 Bight study parsed macroalgae species into more generalized catagories such as red and green macroalgae, whereas the 2010 study by Katz, and Rivera (2012) only included a total of three surveys with 4 macroalgae observations (all *Ulva spp*). In these studies, temporal patterns were variable, with 30% of all macroalgae observations peaking in May 2009, and 20% peaking in September and March 2009. Both studies reported the presence of green algae species during the March and September time frame. The dominant green macroalgae species listed for both studies was *Ulva spp.* There were previously no reports of red macroalgae species within the estuary.

The species observed during this study were categorized into the more general red (*Rhodophyta spp.*), green (filamentous green algae), yellow (*Xanthophyta spp.*), or blue green algae (*Cyanophyta spp.*) to compare with the previous Bight 2008 measurements and summarized in Table 27, with relative contributions to each category provided in Figure 54. Similar to McLaughlin et al., (2012), macroalgae observations were dominated by the presence of green algae at 74% of total observations, with peak observations occurring predominantly in September 2014, January through March 2015, and again in March 2016. Red algae were not as common, making up ~24% of the total observations with peak observations in September 2014 and January and November 2015. The presence of red algae in this study may be related to type of survey conducted (modified floating method vs. intertidal quadrat approach) as well as differences in overall environmental conditions from prior studies such as less scouring, extended periods of mouth closure and less fresh water influx.

Prior research suggests that the observed temporal changes may be related to differences in growth rates of each species type under varying conditions. (For example, green algae growth patterns (the more opportunistic class of macroalgae) are believed to be associated with having a greater tolerance

to both light and air exposure, have a faster growth rate, generally take up nutrients faster, and preferentially grow in calmer waters (Giovani et al., 2014; Fatemi et al., 2012; Kraufvelin et al., 2010; Prathep et al., 2007; Zou, and Gao; 2004; Andria, Brun, Pérez-Lloréns, and Vergara, 2001). Red and brown macroalgae have been observed to be relatively slower growing and more persistent under low nitrogen conditions (Pedersen, M.F. and J. Borum. 1996; Nelson, 2009; Kraufvelin et al., 2010).

Green algae generally decreased up the estuary while red and yellow algae increased up the estuary with the associated environmental conditions. The relative contributions of each category by percent total observations for each station is summarized in Figure 55.

Submerged Aquatic Vegetation- A true SAV survey as described in the 2008 Bight study (McLaughlin et al., 2013), was not conducted but rather percent cover and species identification was included as part of the macroalgae survey described previously. In addition, a true evaluation of seagrasses was also not feasible under the scope of this effort. With the exception of *Ruppia spp., most* SAV species observations at the six monitoring stations weremore incidental , typically as single or unattached stems. As such, beyond a brief summary description, the remaining discussion within this section of the report will focus on the temporal and spatial distributions of *Ruppia spp*.

Results of the monthly SAV observations are summarized in Table 28. The estuary as a whole was rather homogenous relative to SAV with a Shannon-Weiner diversity and Evenness indices for the entire estuary of 1.21 and 0.75 respectively. This would suggest proportion of diversity is driven by a few species. Table 28 shows a total of 172 individual observations, across the six monitoring stations. The most commonly observed SAV by far was *Ruppia spp.* with 87 total observations or 51% of the total observations and 20% of total potential observations over the course of the monitoring period (Figure 56). This appears to be consistent with what has been reported previously for the overall Bight monitoring program though *Ruppia spp.* was not observed in the estuary during the 2008 and 2009 monitoring period (McLaughlin et al., 2013). The least common species observed was *Arundo spp*. and *Salicornia spp.* with a total of 6 and 4 total observations or 3% and 2% respectively

Overall temporal observations of *Ruppia spp.* were quite variable but did show distinct seasonal peaks occurring in October of both 2014 and 2015 (Figure 57), consistent with previous reports. The 2008 Bight study reported *Ruppia spp.* (where present) peaking summer through late fall (July through November) with most of the monitoring segments peaking in September (McLaughlin et al., 2013). A weak positive correlation was observed between the presence of *Ruppia spp.* with salinity and total phosphorous ($R^2 = 0.22$ and 0.23, respectively). The positive correlation to TP is consistent with what has been reported previously by McLaughlin et al., 2013). While no statistically significant correlation between salinity and *Ruppia spp.* were observed in the Bight study they noted an overall correlation between *Ruppia spp.* growth and an increase in fresh water influx into systems with traditional tidal exchange throughout the year (McLaughlin et al., 2013). No other temporal correlations were observed between the presence of *Ruppia spp.* and other parameters measured.

A strong spatial pattern was observed for *Ruppia spp.* across the six monitoring stations. The highest number of observations (48) were recorded at MA6, which equated to 28% of the total SAV observations and 11% of the overall species observations. This equates to 47% of the total *Ruppia spp.* observations being recorded at MA6 (Table 28). The lowest number of *Ruppia spp.* observations were recorded at MA1 and MA2, with 0 and 2 observations, respectively. Strong positive spatial correlations were observed between *Ruppia spp.* and macroalgae percent cover, biomass, and species diversity with R^2 values of 0.7, 0.8, and 0.4, respectively (Figure 58 and 59). This trend has not been

reported previously. No other spatial correlations were observed between presence of *Ruppia spp.* and other measured parameters as all R^2 were less than 0.01.

Table 21. Macroalgal biomass measured in units of g dw/m^2. The collection date represents the first of typically 2 days in which all samples were collected. Blank cells represent conditions when a sample could not be collected. No survey was conducted in May 2015 or February 2016. An "i" indicates the sample was collected using an intertidal protocol. The remainder of samples were collected using a floating protocol (see Section 2.6).

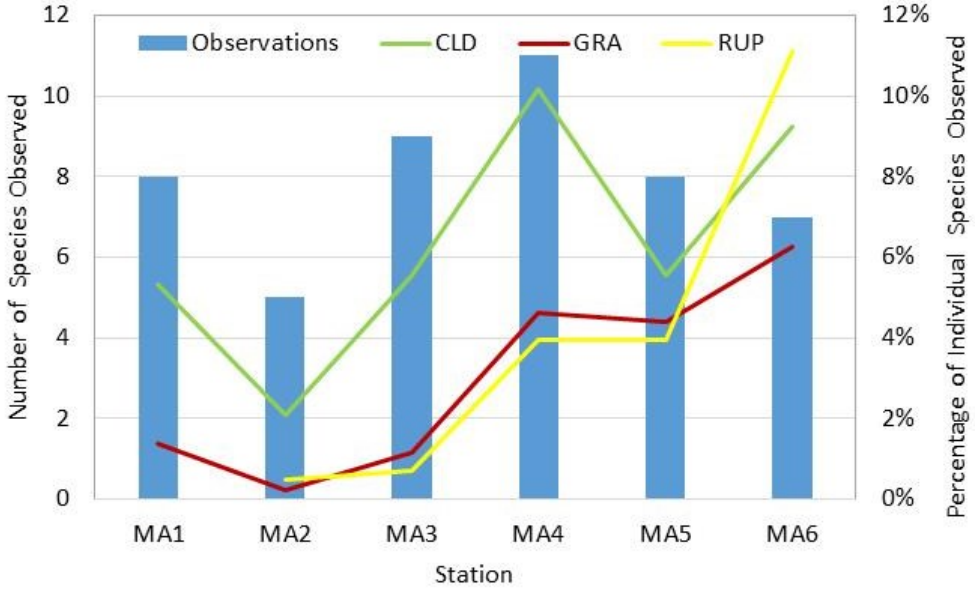

Figure 51. Spatial diversity measured as the total number of macroalgae species observed. The plot includes the average percent observed by station for the two most observed macroalgae: *Cladophora* (CLD) – green line; and *Gracilaria* (GRA) – red line. The average percent observed submerged aquatic vegetation species *Ruppia* (Rup) by station is provided as reference (yellow line).

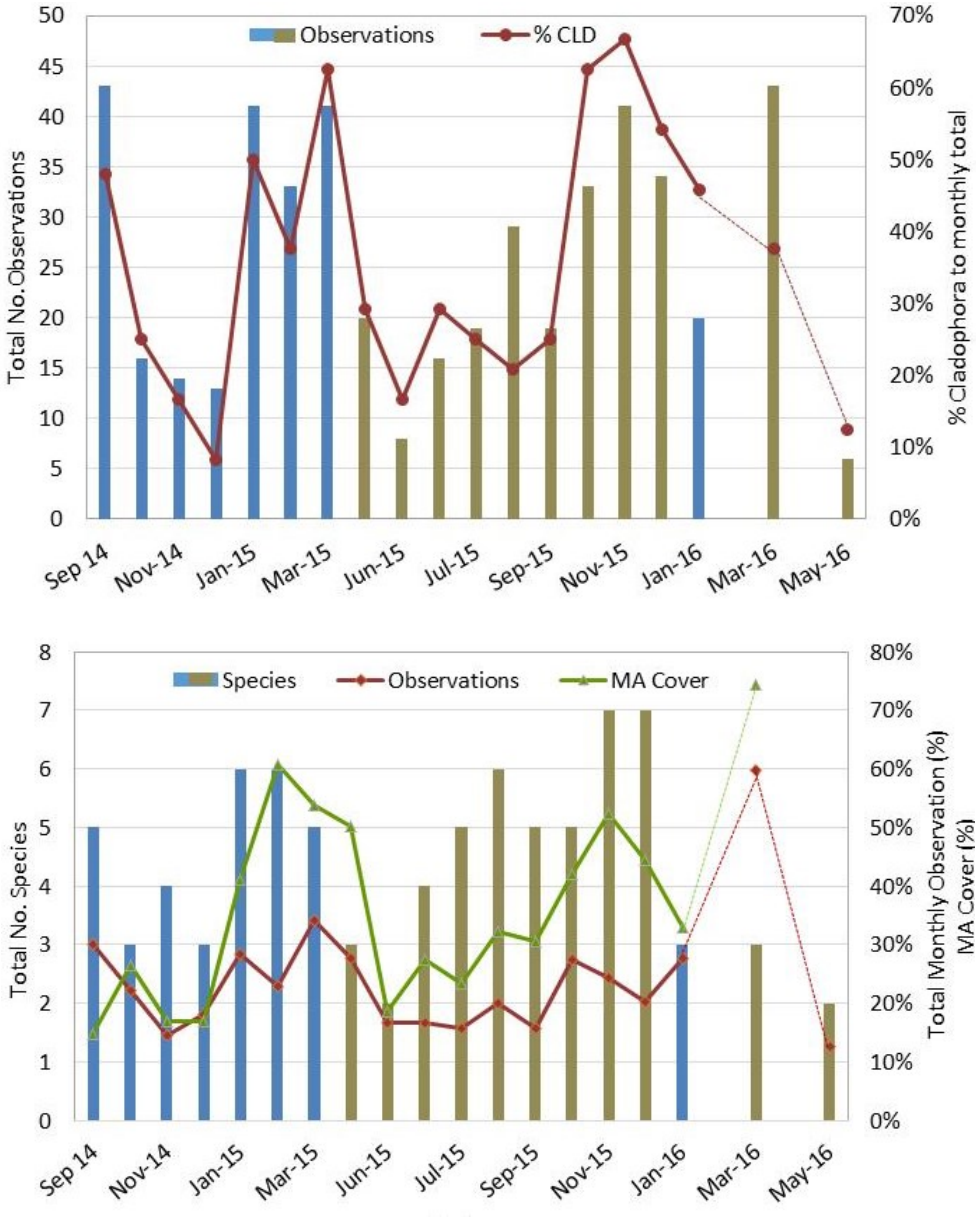

Figure 52. Total number of species observations by month with the percentage of *Cladophora* observations (top). Total number of species by month with macroalgae percent cover. Brown bars indicate closed-mouth conditions while blue bars indicate open-mouth conditions. No samples were collected in May 2015, or February and April 2016.

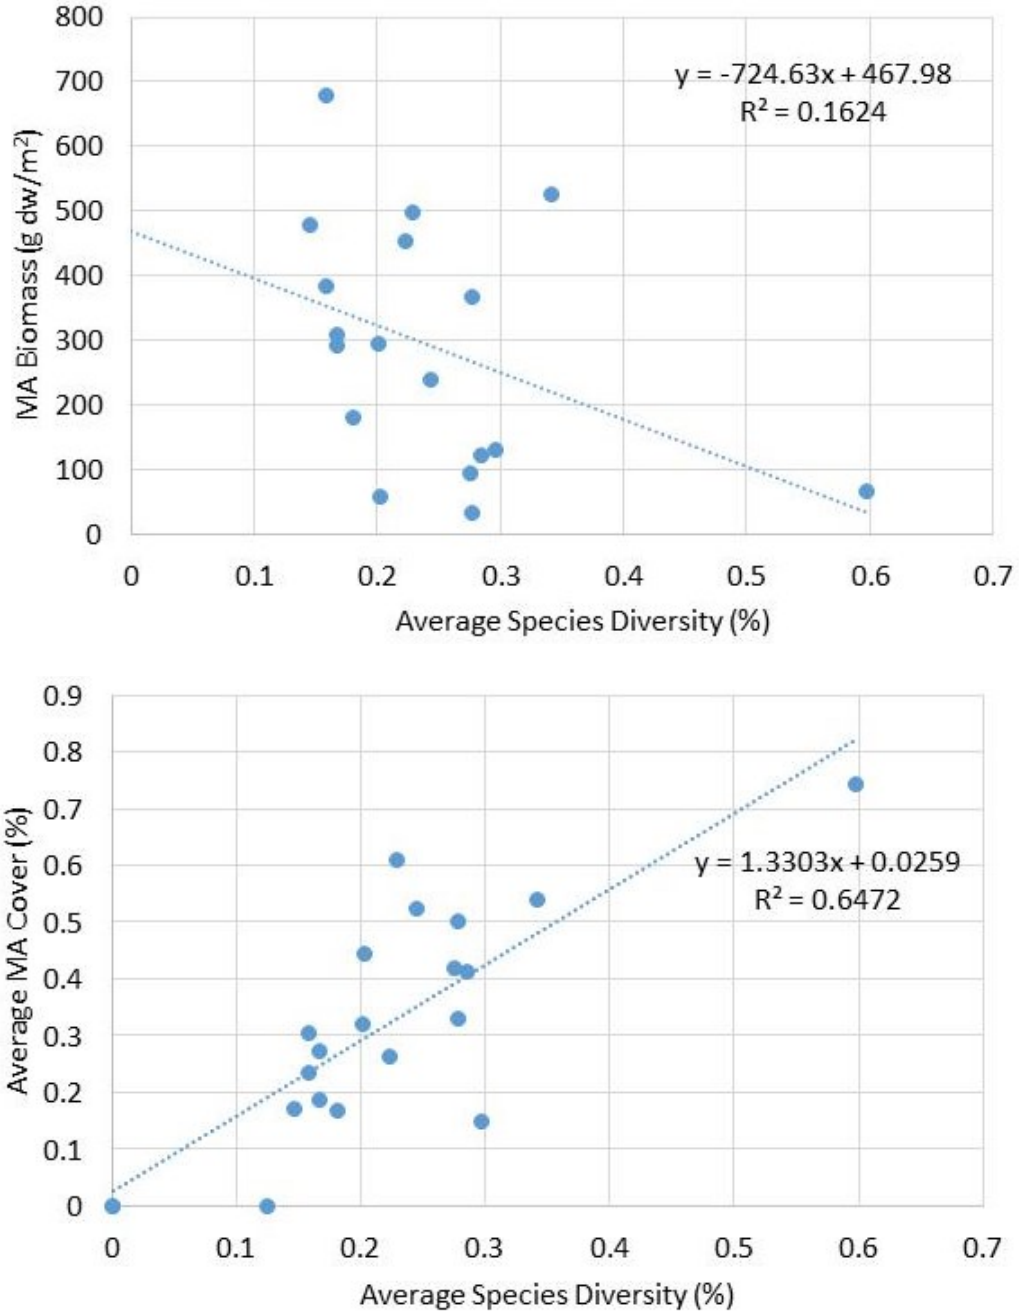

Figure 53. Average percent species diversity vs. average macroalgae biomass (top) and average macroalgae percent cover (bottom) across the entire estuary over time.

Table 27. Generalized macroalgae species categories. Species included in each category listed in table. Note, SAV species *Ruppia spp*. (RUP) was included for comparative purposes.

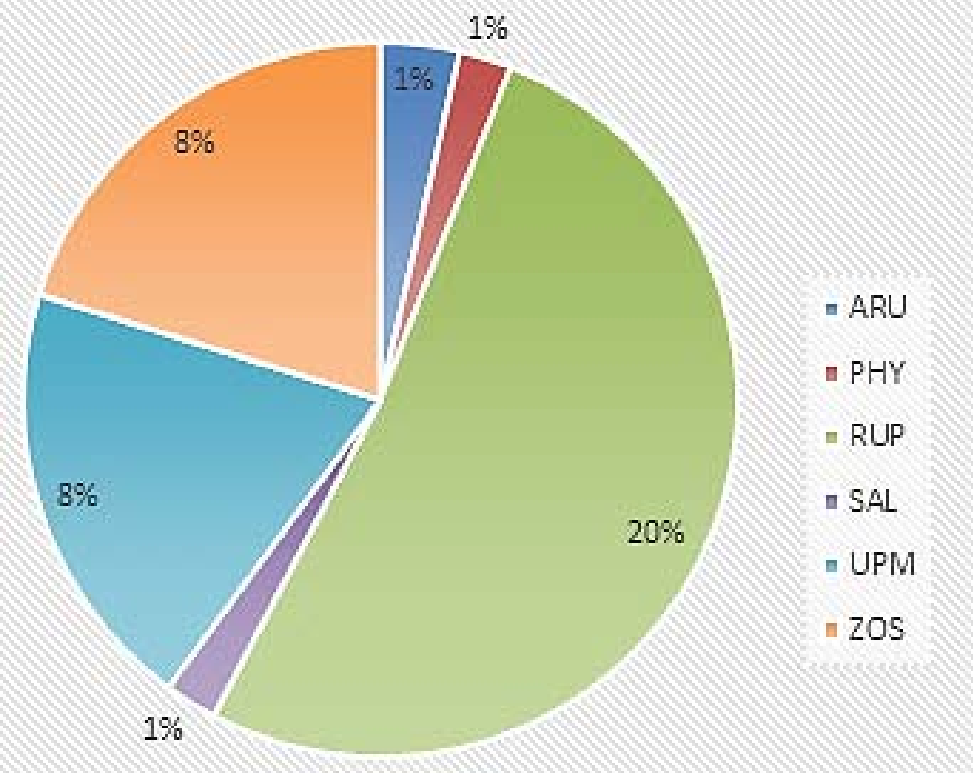

Figure 56. Average frequency of SAV species observed across all stations.

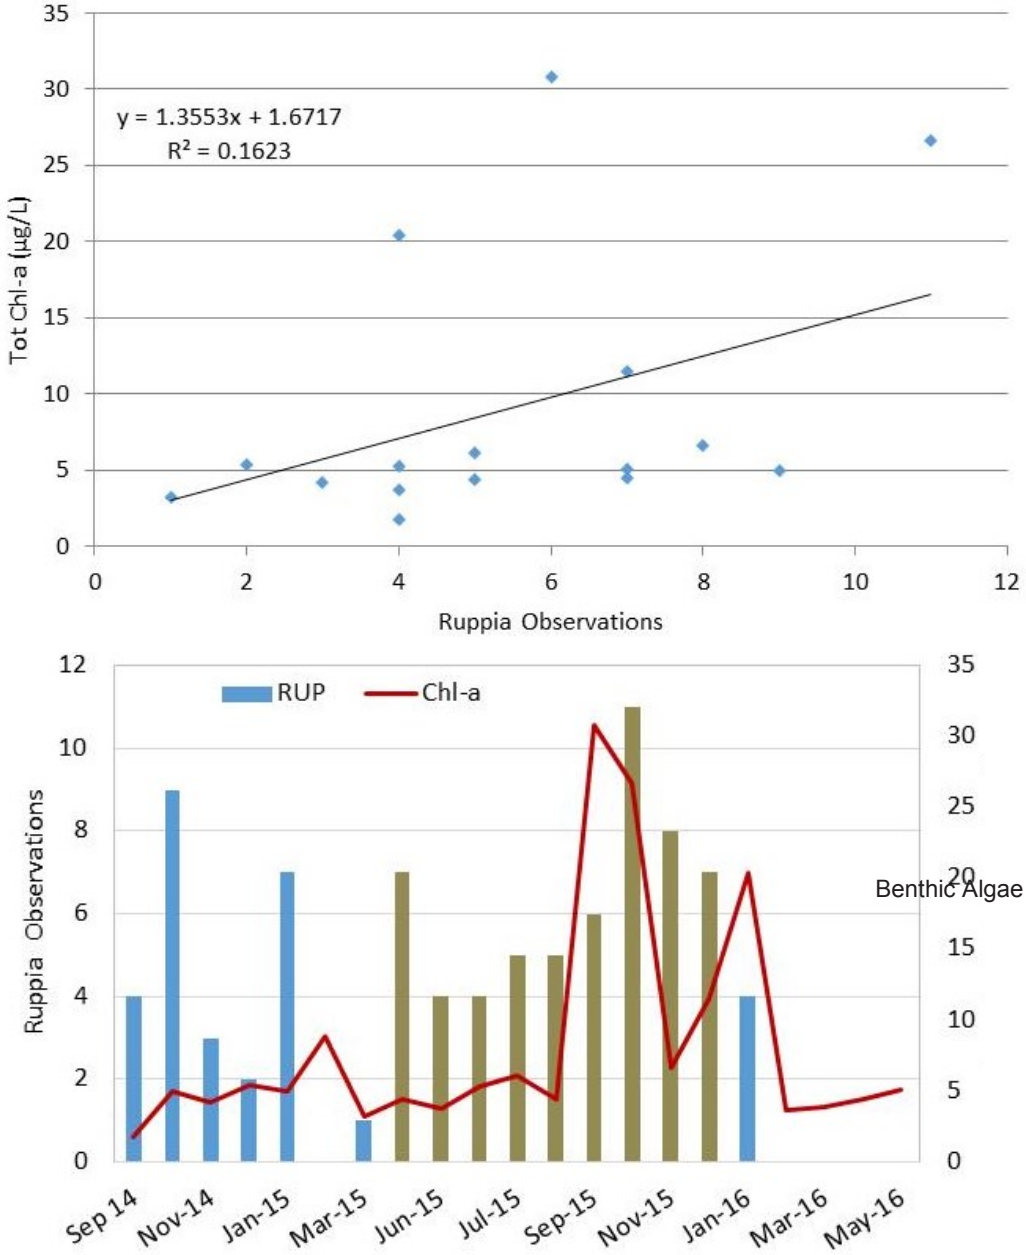

Figure 57. Correlation *of Ruppia* spp. observed across estuary over time to Total Chl-*a* (top). Temporal patterns of SAV *Ruppia* spp. observations (bottom). Blue bars indicate open-mouth conditions while brown bars indicate closed-mouth conditions. Average benthic algae Chl-*a* (µg/m^2) is included for comparison. No samples were collected in May 2015 or February and May 2016.

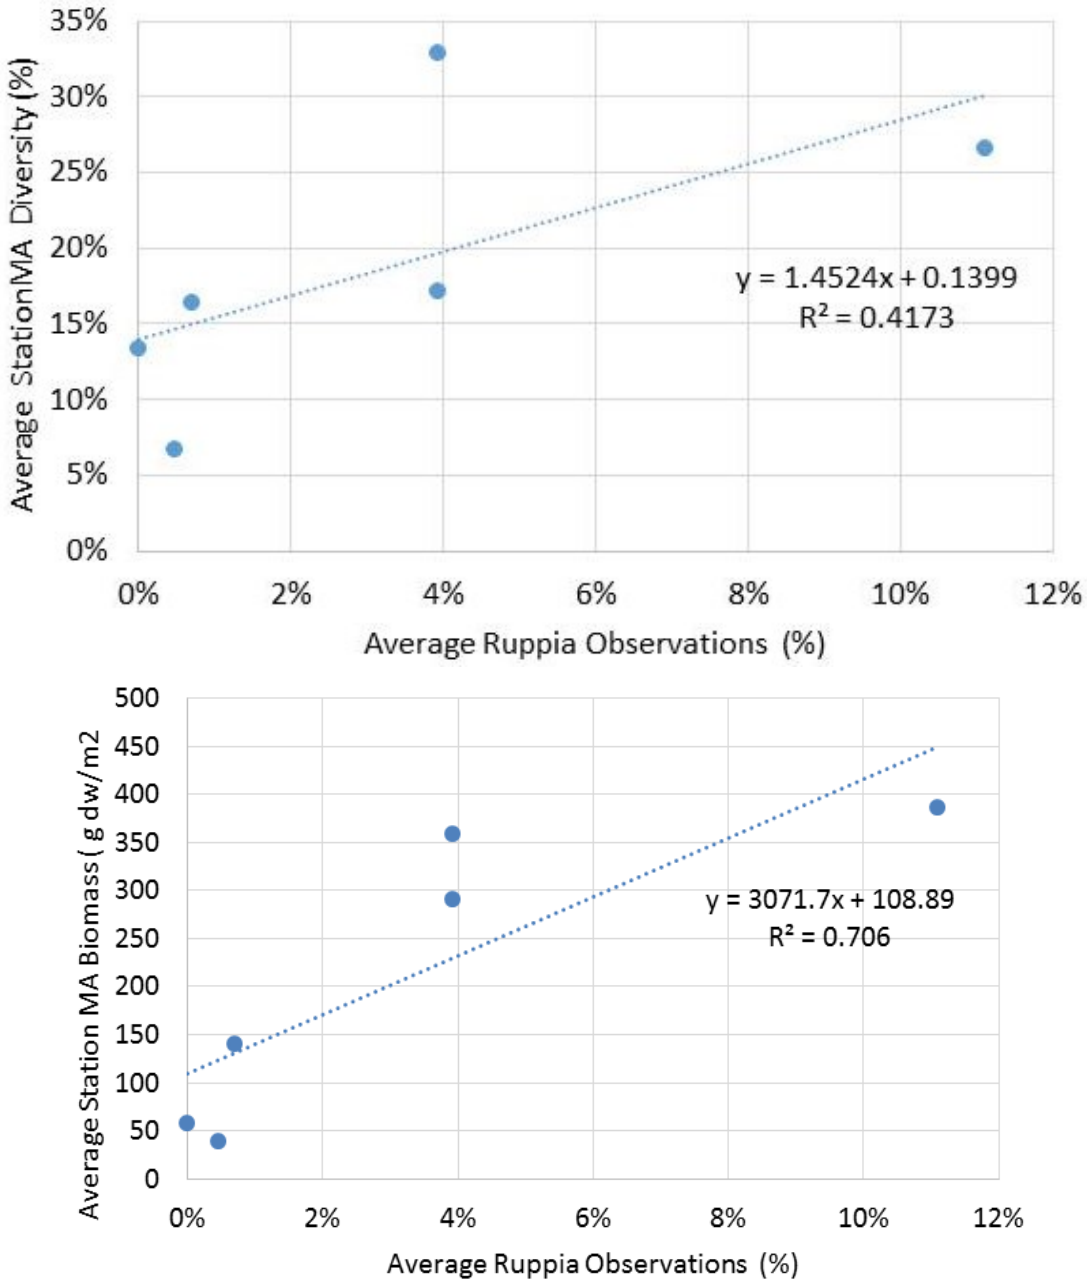

Figure 58. Correlation of average observations of *Ruppia* spp. measured at each station vs. macroalgae diversity (top) and macroalgae biomass (bottom).

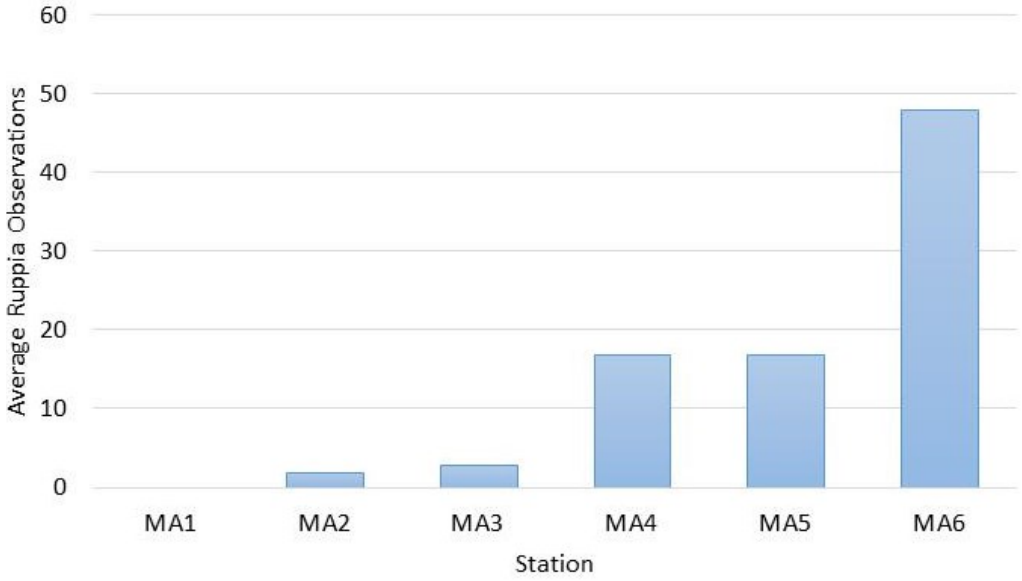

Figure 59. Spatial distribution of *Ruppia* spp. observations.

3.5 MONTHLY BENTHIC ALGAE

Benthic algae Chl-*a* samples were collected during monthly macroalgae surveys. Samples were successfully collected from at least one of the six macroalgae locations during each of the 18 surveys. Table 4 provides a summary of dates and stations for successful acquisition of benthic algal samples. The primary reason for a sample not being collected was directly related to site accessibility, lack of visibility, and/or if the water depth exceeded 0.3 m. Samples were analyzed for total and active Chl-*a* as well as phaeophytin.

The data for the 86 sample analyses are shown in Table 29. The data are shown in chronological order of the date collected. A statistical summary of the benthic algae sample data are shown in Table 30. Benthic algal total Chl-*a* ranged from 12.7 to 466.6 mg/m^2 and averaged 142.8 mg/m^2. Active Chl-*a* ranged from 7.9 to 340 mg/m^2 and averaged 95.2 mg/m^2. Phaeophytin ranged from 2.1 to 263.9 mg/m^2 and averaged 84.4 mg/m^2. The variability of each of the parameters as measured by RSD was roughly in the 60% range both seasonally and spatially. Both active Chl-*a* and phaeophytin were highly correlated with total chlorophyll-*a* ($R^2 > 0.7$).

Benthic algae averaged for all stations during each monthly survey are shown in Figure 60. The benthic algae showed increased concentrations through both springtime periods as well as in the mid-summer period when the mouth was closed. These temporal changes did not generally trend with either macroalgae biomass or phytoplankton.

Benthic algae concentrations generally increased from the mouth (MA1 and MA2) to the middle of the estuary (MA3, MA4, and MA5) and then dropped off again in the upper estuary at MA6 (Figure 61). The drop off in benthic algae further up the estuary suggests that the higher levels of macroalgae biomass and cover may effectively shade the sediment. This spatial distribution was relatively consistent throughout the monitoring period.

The benthic algae percent cover data are summarized in Figure 62. Submerged aquatic vegetation percent cover data are summarized in Table 33 with a statistical summary shown in Table 34. The entire dataset for these parameters are provided in the appendices. These data are plotted along with macroalgae percent cover in Figure 62. The data show a generally higher percent cover for all three during the summer closed-mouth condition but they were not necessarily in sync outside this timeframe.

The station averaged percent cover data for benthic algae was plotted with station average percent cover of aquatic vegetation and macroalgae in Figure 63. The benthic algae cover clearly dropped off up the estuary with the increased cover in macroalgae and subtidal aquatic vegetation, again showing the effects of shading.

Table 29. Benthic algae chlorophyll-*a* results.

3.6 MONTHLY MOUTH BERM HEIGHT

Estuary mouth berm height measurements showed dynamic changes over the 21-month timeframe. Significant changes in beach morphology, including the position of the mouth and elevation of the berm, were observed on each monthly visit. Though the berm height data showed these changes occurring on monthly timescales, the water elevation data indicated that the changes can and do occur more quickly, sometimes on the order of days.

Morphological changes in the sand berm at the mouth were observed throughout the monitoring period. The shape of the water course through the berm changed each visit as it eroded sand primarily on its northern side. Sand bluffs on each side of the water course were observed to erode while on site and frequently resulted in small landslides. The bluffs ranged from only a few inches nearer to the ocean but could be as high as 10’ toward the estuary. Morphological changes continued to occur along the beach when the mouth was closed. On some occasions the ocean formed a ledge on the western edge of the berm and on other occasions there was wetted sand on the shore side of the berm that was clear evidence of overtopping. Examples of these various morphological changes were previously shown in Figure 15 and in Figure 64.

The mouth was open at the start of the monitoring period in September 2014. At that time the mouth opening was located roughly ~ 118 m north of the axial centerline of the estuary (Figure 65). The opening had moved 83 m to the north by the next visit in October, 44 days later. The mouth opening continued to move north an additional 57 m by cutting into the high sand dunes that form the bird nesting area until it reached its maximum extent in March 2015. The estuary mouth effectively closed between 31 March and 23 December 2015, when it reopened 511 m to the south of its March position. The mouth moved another 20 m to the south before it closed up again in February 2016.

Mouth berm elevations for each month are shown in Figure 66. The values represent the maximum elevation where water flowed through the mouth when it was open or the maximum dry land

elevation when it was closed. While open, the berm height ranged from -25 to 98 cm NAVD88. When closed the berm height ranged from 254 to 334 cm NAVD88. The measured beach berm elevation data were compared to an estimate of the berm height derived from 28-day minimum water level data measured in the estuary in Figure 67. As expected, the actual berm heights measured during open periods were lower than the estimates calculated in this manner, while the berm height during closed periods were higher than the estimates. The mouth essentially was closed to tidal exchange when berm heights exceeded ~ 230 cm NAVD88.

3.7 AXIAL MAPPING

Two axial mapping surveys were conducted during the monitoring period to evaluate the spatial variations in water quality in the estuary. The transects were completed on 18 May 2015 and 14 June 2016, both under closed-mouth conditions. The transects were roughly the same on both occasions, starting close to the mouth and zigzagging toward each shoreline while moving along the longitudinal axis. The shallow water near the mouth forced the transects to cross a bit further upstream than originally planned even when using a shallow draft kayak to conduct the survey.

The spatial distribution of salinity, temperature, and dissolved oxygen is shown for 2015 in Figure 68 and Figure 69 and for 2016 in Figure 70 and Figure 71. The plots clearly show that the main gradient was along the axis of the estuary with little in the way of longitudinal variation. The gradients were present even in the absence of tidal mixing.

The spatial distributions of surface salinity and temperature were similar on both occasions, even if the exact levels were not. Temperature increased upstream from ~19 to 28.5 °C. Salinity generally decreased upstream from ~36 psu to 31 psu in May 2015 and from ~39 to 18 psu in June 2016. The gradients appeared steepest in the upper reaches of the estuary where the water was warmer and fresher than nearer to the mouth. These distributions suggest that there is a source of freshwater at the top of the estuary, whether from groundwater or surface water. The freshwater source appeared to be a bit stronger in June 2016, though this transect went a bit further upstream than the May 2015 survey transect.

The distributions of dissolved oxygen were not similar for the two periods. The May 2015 distribution showed an increasing gradient upstream from ~5 to 12 mg/L while the June 2016

distribution showed a decreasing gradient upstream from ~7 to 3mg/L. The gradient again appeared to be steeper in June with overall concentration levels that were about half those seen in May 2015. Like temperature and salinity, the pH distributions for both periods were relatively similar to each other though with a decreasing gradient upstream from ~8.3 to 7.6. The steeper gradient of pH observed in June 2016 was similar to the other parameters.

The observed spatial distribution during these two surveys was generally comparable to measurements made previously in 2010 (Katz and Rivera, 2012) and 2006 and 2007 (Katz, 2007). A much steeper gradient in salinity was observed in 2010 under a recently closed-mouth condition with a freshwater signature observed down to the I-5 Bridge (Figure 72). This correlates with an overall higher freshwater loading observed during that year as well (Figure 21). Higher temperatures were observed on most surveys except in March 2010 when there was a slight decrease. In general there was not a strong spatial gradient of dissolved oxygen in the estuary. The data varied with each survey and appeared to reflect larger differences related to the time of year, time of day, tide, and open or closed-mouth condition.

3.8 BATHYMETRIC SURVEY

The bathymetry of the estuary was measured in May 2015 along the survey track shown in Figure 73. The data included 32820 data points. A contour map of the elevation data is shown in Figure 74 in meters relative to mean sea level (MSL). The average depth relative to mean sea level was 0.25 m. The maximum depths were measured at the two bridges with a maximum of 4.6 m (MSL) measured at the Stuart Mesa Bridge. The next deepest area was at the I-5 Bridge with depths of 3.7 m (MSL). The area nearest to the mouth was too shallow to measure with the echosounder. Water depths in that region were less than 0.3 m, even though the mouth was closed and water levels were relatively high. The data are provided in the appendices on the accompanying CD.

The bathymetry data were very similar to the data collected in 2013 (Figure 75). The average difference in depths measured in 2015 and 2013 was -0.16 m, suggesting that estuary may have filled slightly over the 2 years, though the difference is small enough to be within the level of measurement, data interpolation, and grid math processing error. The largest depth differences between the 2 years, as much as 4 meters, were observed in the area near the I-5 Bridge (Figure 76). The differences there are most likely related to the presence of a large earthen dam during the 2013 survey to support reconstruction of the Railroad Bridge and its subsequent removal before the 2015 survey. The relatively small overall differences in depth profiles between the 2 years are consistent with reduced rainfall and no major storm flow events that might move sediments around or out of the estuary. As such either dataset could be used for future modeling efforts.

4. MONITORING RESULTS SUMMARY

The current monitoring expanded on previously collected datasets by (1) extending the length of continuous monitoring from two or four one-month index periods to a 21-month timeframe; (2) expanding from quarterly to monthly collection of discrete water parameters, macroalgal biomass, cover and adding macroalgal speciation and carbon, nitrogen, and phosphorous content; (3) adding benthic algal Chl-*a*, cover, and submerged aquatic vegetation cover; (4) expanding the number of monitoring locations and number of analytes; (5) continuing with spatial mapping; and (6) adding measurements of water level, mouth berm elevation, and bathymetry. Similar to previous studies, additional ancillary datasets associated with current time frame, were collected including; local climate, river gage, tides, waves and storm water samples so as to provide context for the monitoring observations. This also included recent measurements of groundwater nutrient loading along the north shore of the estuary adjacent to the I-5 Bridge. As such, the current monitoring represents the most comprehensive water quality dataset collected in the estuary to date.

Because of the magnitude and complexity of the dataset, the following summary is provided to summarize the key results described in the previous section.

***Data Integrity*.** The monitoring was extensive and included the collection and analysis of over 121,000 continuous water quality data records, as well as hundreds of monthly discrete water and algae measurement data collected over 32 field visits and 6 monitoring stations. With some exceptions, the dataset was of very high quality. Up to 30% of the DO data were compromised from sensor fouling and required calculation adjustment. These were instances when oxygen sensor response was reduced and difficult to pick up even when monitoring the data on a daily basis. These data were corrected using a time-weighted calculation adjustment. About 10% of the data could not be corrected and were removed from the dataset. Up to half of the macroalgal biomass measurements may have included as much as 25% submerged aquatic vegetation biomass resulting in potentially overstated values. However, the SAV by themselves play a role in primary production, oxygen production and respiration. Nearly all macroalgal biomass data were collected under non-intertidal conditions, which have an unknown effect on the final quantitation relative to standard intertidal protocols. A few discrete nutrient samples appeared to be incorrectly labeled and the data were reassigned to different stations using best professional judgement.

***Exchange with the Ocean*.** The lack of exchange with the ocean during most of the monitoring period was the key driver for the observed water quality conditions. The estuary was open for the first 6.5 months (September 2014 through March 2015) and then closed for the next nine months when it opened for a brief two months (December 2015 through February 2016) and then closed for the remainder of the monitoring period (June 2016). The mouth was closed 61% of the monitoring period and most critically during the summer of 2015. Even when open the tidal exchange was limited by as much as 50% from phase lag with the tide, a result of slow discharge through a narrow shallow berm. Berm heights above ~230 cm NAVD88 resulted in closed conditions except for the occasional overtopping by waves at high tide. The mouth opening location and berm heights can be controlled as much by tides and waves as by river flow and were observed to change in a matter of days.

***Climate Effects*.** Freshwater flow during the monitoring period was reduced from past years as a result of lower rainfall amounts. Annual average rainfall over the past 4 years was lower than the previous 4 years by 55%. The impact is that the annual average freshwater discharge to the estuary through the Ysidora gage dropped by a factor of 9 over that period and was a factor of 9 lower than the past 23-year average. The low river flow conditions aided in the process of beach berm building at the mouth that eventually resulted in it closing completely to exchange with the ocean. The low

freshwater input also resulted in very limited swings in salinity even when there was tidal exchange. The signature of low freshwater was confined to the area well above the Stuart Mesa Bridge in the upper reach of the estuary when in past years the freshwater signature was clearly present at the I-5 Bridge. The presence of freshwater at the top of the estuary in the summer of 2016, without recent rainfall and no flow through the Ysidora gage, is consistent with the input of watershed groundwater, though this has not yet been independently validated. Another effect of low rainfall and flow was the lack of significant changes in bathymetry of the estuary since its measurements in 2013.

Water Quality. The key impact on water quality conditions during this monitoring period was related to the open or closed condition of the mouth, and thus, lack of exchange with the ocean. Closure during the summer of 2015 resulted in maximum temperature (31.6 °C) and salinity (41.4 psu) as a result of solar insolation and limited freshwater input. These values represent the highest values measured in the estuary since 1996 (USGS gage 11046050, Katz 2007, 2012, SCCWRP 2013). On average, temperature and salinity were 29% and 11% higher under closed-mouth conditions, respectively. With no exchange, the effect of the gradual summertime increase in temperature and salinity along with a few surface water storm flows, and watershed groundwater flow led to an overall general increase in nutrients and algae. The summer closed-mouth condition was characterized by higher daily swings and an overall decrease in dissolved oxygen concentrations. Part of the decrease, ~1 mg/L, was attributable to the increased salinity and temperatures. The large swings were associated with increased productivity and respiration driven by primary productivity and higher oxygen demand. The impact of the closed-mouth condition resulted in a substantially higher frequency when dissolved oxygen concentrations dropped below 5 mg/L, 28.2% versus 9.3%.of the time.

Nutrients. Maximum concentrations of TN (2.1 mg/L) and PN (1.1 mg/L) were observed during summer closed-mouth summer conditions as were all the nutrients except particulate nitrogen and carbon. Average values of TN and TP were 2.2 and 3.5 times higher during these conditions even though storm loading was ostensibly much higher during open conditions. All but one sample had TN concentrations that exceeded the Basin Plan Objective of 1 mg/L, which occurred during the closed-mouth summer period. During this period, all values of TP were above the Basin Plan Objective of 0.1 mg/L though 50% of values were also above the objective when the mouth was open. Average monthly TN and TP concentrations were highly correlated with one another ($R^2 = 0.79$) suggesting similar sources or processes. The estuary wide spatial distribution, measured over time or on axial surveys, showed higher TN and TP concentrations up the estuary consistent with watershed sources. The spatial distribution flattened or decreased up the estuary under closed conditions likely as a consequence of higher algal uptake. Approximately 90% of the nitrogen was found as organic nitrogen, while ~68% of the phosphorous was found as inorganic phosphorous. The balance of these nutrient species and their role in impacting algal growth and eutrophication is not well understood and still an active area of study in estuaries (Seitzinger and Sanders, 1997; Buzzelli, Wan, Doering and Boyer; 2013).

Macroalgae. Biomass concentrations were patchy with high values observed during both open-mouth winter/spring and summer closed-mouth conditions. The blooms in winter/spring appeared associated with nutrient influx during storms followed by a short closure and very warm, sunny conditions. The blooms in summer appeared associated with the general build-up of nutrients during the summer closed-mouth condition. Macroalgae biomass concentrations and percent cover were a maximum (893 g dw/m^2, 100%) during summer closed-mouth conditions while minimum values (0.0 g dw/m^2, 0%) were measured during open-mouth relatively high discharge conditions. The lows appeared tied to potential scouring during and after storm flows. Macroalgal biomass increased up the estuary and was higher at the three upstream stations than the three stations in the lower estuary.

The overall average biomass concentration was 213 g dw/m^2 with considerable temporal and spatial variability (RSD = 114%). The estuary-wide average value for each visit ranged from 27 g dw/m^2 in January 2016 during open-mouth conditions to 510 g dw/m^2 in September 2015 under closed-mouth conditions. Though peak biomass was observed during the summer closed-mouth condition, on average, open-mouth conditions were slightly higher than closed (230 vs. 201 g dw/m^2).

Macroalgae speciation was quite variable throughout the study. The macroalgae was predominantly composed of green algae species, though there was a persistent low level of red algae throughout the monitoring period. The presence of red algae has not previously been reported, which may be related to variations in method of collection (modified floating vs. intertidal mudflat) but also overall conditions of the estuary (i.e. drought, less scouring, mouth closure for extended periods, and less fresh water influx). Peak observations of green algae coincided with periods of peak macroalgal percent cover. Generally during the winter months, species diversity tended to increase as macroalgae % cover tended to increase, but had a slight decline when biomass levels increased. While average diversity was similar between an open and closed-mouth condition (M = 4.38 vs. 4.46) variability was slightly higher (RSD = 41% vs. 30%) in a closed-mouth condition. Overall there was a higher degree of diversity observed between the I-5 and Stuart Mesa bridges with the greatest abundance of observations occurring in the upper half of the estuary (MA4-MA6). Excluding a slight association to salinity (R^2 0.22), species diversity was not highly associated with any of the other monitored parameters.

Benthic algae measured as Chl-*a* and as percent cover had a patchy temporal distribution that did not generally trend well with either macroagal biomass, phytoplankton Chl-*a*, or subtidal aquatic vegetation, yet had a slight positive association to species diversity. Benthic algae concentrations increased up the estuary similarly to macroalgae, with peak levels primarily observed at MA4 and MA5. The falloff up the estuary was likely associated with shading by higher levels of macroalgae and subtidal aquatic vegetation.

5. DISCUSSION

The goal of this most recent monitoring was to provide a comprehensive dataset of current water quality conditions in the estuary related to nutrients, algae, dissolved oxygen, and eutrophication. Historic measurements led the SDRWQCB to list the estuary as impaired for eutrophication in 1986 based on eutrophication, a condition that results from excessive nutrients that leads to a depression in dissolved oxygen. The San Diego Basin Plan Objectives include nutrient limits of 1 mg/L total nitrogen or 0.1 mg/L total phosphorous and dissolved oxygen concentration of less than 5 mg/L. The SDRWQCB, together with stakeholders, have been working to develop an alternative set of regulatory metrics based on the Nutrient Numeric Endpoint (NNE) framework that is focused on the ecological response indicators of macroalgae biomass and dissolved oxygen. The benchmarks under consideration were derived from evaluations of water quality datasets collected in 2008 and 2009 as part of the Regional Board's investigative order (R9-2006-0076) and results of a linked hydrodynamic and water quality model calibrated for the above dataset (Wang, Katz, Barua, Martin, and Wool, 2016). This most recent data collection provides not only an evaluation of current conditions but also allows an evaluation relative to the historic record and to the likely regulatory benchmarks.

This study and previous field studies have consistently shown the Santa Margarita estuary to be a highly dynamic water body with water quality conditions that are tied primarily to seasonal changes in rainfall, freshwater discharge, summertime heating, and changes in tidal exchange with the ocean as a result of natural berm building at the mouth. These factors result in spatial variations that occur primarily along the longitudinal axis of the estuary, which shows a predominantly oceanic regime west of the I-5 Bridge, a freshwater regime east of the Stuart Mesa Bridge, and a transitional area between them. The magnitude and extent of these processes directly impact the level of nutrient loading and resultant algal growth and dissolved oxygen levels.

Conditions measured in this recent monitoring were significantly impacted by the 9-month duration of a completely closed-mouth in summer, by limited freshwater flow, and by relatively limited exchange with the ocean when the mouth was open. The outcome was one in which the estuary became warmer, saltier, and accumulated nutrients through summer and responded with an increase in macroalgae, benthic algae and phytoplankton as well as a general reduction in dissolved oxygen levels. Key closed-mouth summertime effects are clearly shown Figure 77 through Figure 80. The increase in nutrients by factors of between ~4 and 13 for TN and TP respectively, was a direct result of the closed condition that allowed nutrients to accumulate through a combination of remineralization or sediment diagenesis as well as from storm water runoff events (Figure 80) and unmeasured inflow of watershed groundwater. The slow buildup in nutrients along with decrease in TN:TP appeared to be consistent with the gradual increases in temperature and salinity, suggesting that remineralization was a dominant process, observable mainly because the mouth was closed. The increase in nutrients was well correlated with the increase in macroalgae biomass (Figure 81) when plotting the overall average concentrations of TN, TP, and MA biomass measured at the MA1, MA3, and MA6.

The relative contributions of the various nutrient sources cannot be determined without additional loading data from sediment flux, watershed groundwater, and storm water. No sediment flux measurements were made as a part of this study and the few data available for this source were highly variable (McLaughlin et al., 2013). Few nitrogen and no phosphorous concentration data, or direct measures of flow have been made of the groundwater entering in from the watershed, though monitoring is underway by Camp Pendleton. Storm water data are available for the 2014 and 2015 timeframe but were limited to a single storm in December 2014 when the mouth was open.

The impact of increased algal biomass in the estuary during the closed-mouth condition in summer resulted in a general decrease in daily average dissolved oxygen values as well as larger daily swings (Figure 79). As described earlier, these conditions led to a significantly higher percentage of the dataset with dissolved oxygen values below 5 mg/L (Table 18). Dissolved oxygen (DO) values fell below 5 mg/L 9.3% of the time during open-mouth conditions and 28.2% of the tine during closed-mouth conditions. The overall frequency of DO below 5 mg/L was 21.1 %, a value that would result in the estuary being ranked as a median California estuary (Sutula et al., 2016).

An examination of the DO dataset indicates that the levels remain below 5 mg/L for an entire day ~1% of the time at the I-5 Bridge and ~7% of the time at SMB. Examples of values going below 5 mg/L for both partial and full days are shown in Figure 82 and Figure 83. This occurred on three occasions at the I-5 Bridge for up to four days and on 14 occasions for up to 7 days at the Stuart Mesa Bridge. The occurrence of DO less than 5 mg/L for more than a 24-hour period was not tied to closed-mouth conditions, but did appear to be tied to periods of higher macroalgal biomass levels. It is not known how the estuary compares to reference estuaries in terms of continuous periods of low DO values. As a reminder, the higher rate and degree of fouling that occurred during the summer clearly compromised DO measurements during this period and required calibration adjustment.

The two benchmarks under consideration for the TMDL are tied to macroalgal biomass and dissolved oxygen. The thresholds that have been identified are currently based on application of the water quality modeling work of Wang et al., (2016) and described in the model application report by (SCCWRP,2016). In particular, the relationship between maximum macroalgal biomass and minimum daily dissolved oxygen was used to derive a threshold value of 57 g dw/m^2. The dissolved oxygen threshold was based on meeting 5 mg/L in the 10^{th} percentile of a 7-day average of the daily minimum concentration.

The current set of conditions in the estuary did not meet these two thresholds at all locations or at all times, particularly during the summer dry period for which they are expected to apply. Macroalgal biomass values exceeded the 57 g dw/m^2 threshold in 57% of samples overall, and 61% during the critical period. Lower estuary stations west of the I-5 Bridge exceeded the threshold ~30% of the time during the critical period, while 80% of samples in the upper estuary, east of the bridge, exceeded the threshold. There were clearly periods of time when dissolved oxygen levels at both bridges would not have met the 5 mg/L threshold, though the frequency of exceedance was considerably lower in the lower estuary than in the upper estuary.

An evaluation of the relationship between DO and macroalgal biomass that was used to derive the macroalgae threshold in the model application report (Sutula et al., 2016) was conducted for the current dataset. The daily minimum oxygen value measured at either of the two buoy stations is plotted against the maximum macroalgal biomass data measured on the same date in Figure 84 for summer closed-mouth conditions. The regression indicates that the level of macroalgae that can be present and still meet the dissolved oxygen daily minimum of 5 mg/L is 129 g dw/m^2 though the relationship was not highly correlated ($R^2 = 0.30$). This value is a factor 2.2 higher than the threshold determined in the model application report. Even if the macroalgal biomass concentrations were overestimated 25% (maximum) by the inclusion of SAV, an estimated level of algal biomass of 97 g dw/m^2 would still be 70% higher than the threshold derived in the model application report. It should be noted that the SAV biomass during parts of the year was potentially high enough to have played an important role in the oxygen dynamics.

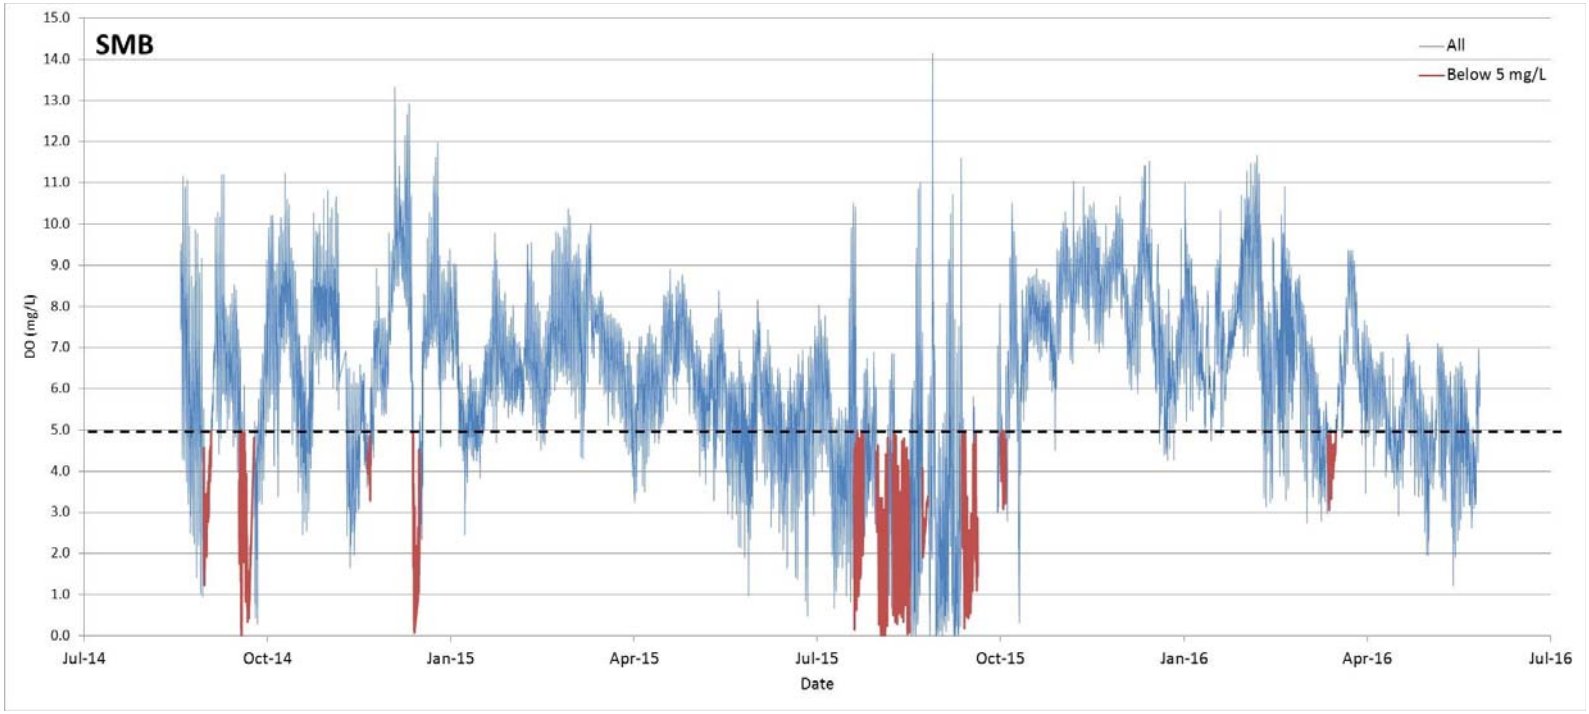

Figure 83. Dissolved oxygen concentrations measured at the Stuart Mesa Bridge. The values shown in red are for times when DO went below 5 mg/L for more than 24 hours. This occurred on 14 occasions for up to 7 days

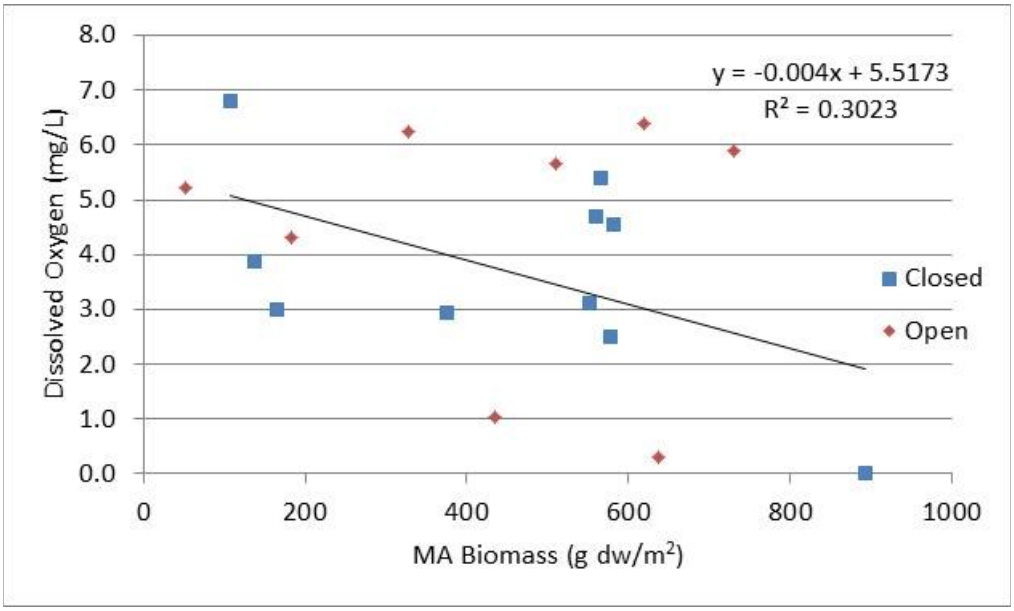

Figure 84. Maximum monthly macroalgae biomass vs. daily minimum dissolved oxygen concentrations measured during closed-mouth conditions (blue squares). The regression line crosses 5 mg/L at a macroalgae biomass concentration of 129 g dw/m^2. The red points on the plot show data for open-mouth conditions.

Comparisons of the data collected as part of this monitoring effort were compared to past field surveys by SSC Pacific in 2006 and 2007 (Katz, 2007), by SCCWRP in 2008 and 2009 (McLaughlin et al., 2013), and by SSC Pacific in 2010 (Katz and Rivera, 2012). Average total nitrogen, total phosphorous, and macroalgae biomass, and cover for the four timeframes are shown in Table 36 and in Figure 85 and Figure 86. Average ambient total nitrogen concentrations have dropped a factor of 6 since 2007, from 4.3 mg/L to 0.66 mg/L. Comparable values of total phosphorous from 2008 to 2015 (TP was not measured in 2006) have remained about the same with a marginal increase of ~12% from 0.26 to 0.29 mg/L. Over the same period, macroalgae increased fivefold while cover has increased by 30%. For all 3 years the highest biomass concentrations were found during late summer, and in 2010 and 2015 were associated with closed-mouth conditions. The increases over time appear to connect more to flow and exchange conditions with mouth dynamics rather than nutrients.

The decrease in ambient nitrogen levels reflects two main changes; reduced overall freshwater and nutrient load from the watershed (Figure 20) and reduced inflow of groundwater entering into the estuary at the I-5 Bridge. The relatively high ambient nitrogen levels that were associated with winter/spring runoff conditions in historic datasets were not observed in this latest dataset. This is presumably due to the reduced overall water flow if not also nitrogen concentrations. Perhaps more importantly, the reduction in ambient nitrogen concentrations appear tied to reduction in groundwater loading entering the estuary from the historical agricultural fields near to the I-5 Bridge. The high average nitrogen value measured in 2006 and 2007 was a result of over a dozen ambient samples with TN concentrations of between 15 and 31 mg/L. High ambient TN concentrations of up to 80 mg/L were also observed by CDM in 2008 (CDM, 2009). These elevated values reflected a discharge of high nitrogen groundwater directly into the estuary along the northern shore under the

I-5 Bridge. In 2006, groundwater was getting pumped directly into the estuary as an intermittent surface water flow by a North County Transit District groundwater pumping station. This surface flow had a TN concentration of ~80 NO3-N mg/L (Katz, 2007). Investigations by SSC Pacific in 2010 (Leather et al., 2015) showed that groundwater associated with the agricultural field along the northern shoreline by I-5 was discharging directly into the estuary as an advective groundwater flow with NO3-N concentrations up to 80 mg/L (upland values were as high as 168 mg/L). This groundwater nitrogen load was estimated at 3.5 kg/d based on a flow of up to 12 cm/d to the estuary Leather. The agricultural field was fallowed in 2007 and has been monitored on several occasions in 2010, 2012, 2013, 2014, and 2016 (Leather et al., 2016). Measured groundwater concentrations and estimated flow rates have steadily decreased since 2010 and were most recently measured at ~10 mg/L NO3-N and 5 cm/d flow resulting in an estimated nitrogen loading of 0.09 kg/d in May 2016. This 40-fold reduction in load has likely been a key factor in the overall decrease in ambient nitrogen concentration levels in the estuary over the past 10 years.

The long-term drop in ambient concentrations of nutrients over the past 10 years has not resulted in a concomitant decrease in macroalgae. In fact, the opposite has occurred as demonstrated in Figure 87. The biomass increases over time appear to be related more to the limitations in flow conditions than to nutrients. These higher levels have been observed in other low or no flow estuaries around the state (Sutula, personal communication).

Table 36. Average total nitrogen, total phosphorous, macroalgae biomass and cover for samples collected in 2006 and 2007 (Katz, 2007), 2008 and 2009 (McLaughlin et al., 2013), 2010, (Katz and Rivera, 2012), and 2014 through 2016. NA = not measured.

14. ABSTRACT

This report describes current water quality conditions in the Santa Margarita Estuary monitored over a 21-month period between September 2014 and June 2016. The data collection was designed to assess current water quality conditions as they relate to eutrophication, as well as to compare to historical monitoring datasets collected over the past 10 years. The data were collected by the Navy's Environmental Sciences Branch of the Space and Naval Warfare Systems Center Pacific for Environmental Security, Marine Corps Base Camp Pendleton. This report describes the background, technical approach, methods, and results of collected data with a summary and analysis of water quality and the dynamics and main physiochemical processes that control it.

Math Survey Notes from 9 Sep 14

Leslie, Chuck, Kyle (RSO) ##2m Botanic Rods down to roundpole flush with sand surface #

1548 Get Position @ corner pole of Fence bordering bird area
Pole has signage ~ Point 1
Point 2 taken on high berm area 2-3' higher than area to south

1552 Start Transect to south. Positions taken close together when berm is steep, otherwise using ~2m steps interval (2 Steps)
Compass ~ 180° Water still flowing

1612 End Transect on dry flat sand

Note: Water levels up to thigh high w/ flow really strong out

1613 Transect 2 to North Heading 308° (~10 m to West)

1630 End on N. Berm Water still flowing out strongly

1632 Transect 3 to south Marsh elev. are eastward closer to estuary 125°

1650 End Transect

1654 Transect 4 ~ move toward ocean ~ cross to south

~~Start~~ Transect 5 ~ cross to N ~ flatter part of beach by ocean
taking more steps 7-10 between points on flatter section

End ~ 1710 Water still flowing out but much slower
Sand berms on edges have in constant decay ~
breaking off & falling into water. Some ~ 5' high

@ 1800 ~ Check on MA6 ~ still under water

1500 – 1700 Monthly Buoy & Ocean Water Sample

Summary 18 Dec 2014

Algal Sampling Summary:

	Tidal	Floating	Sediment	Water SAMPLES
MA6	N	Y	N	Y
MA5	N	N	N	N
MA4	N	N	N	N
MA3	N	N	N	Y
MA2	N	N	N	N
MA1	N	N	Y	Y

~~Tide level~~

Marsh Survey – 3 markers on SM Bridge
– Perimeter of water course
– 3 Transects across to previous survey locations
– Water course shifted ~50 cm to North again
– Wider basin interior to higher + gentle curving course
– Water flowing pretty strong, Finished as tide came in

CTD Cal ✓ – SM Bridge – ~~all good~~ pH needed recal - low pH 4
IS Bridge – all good

Water Collection – Ocean (using bucket collection method) + Sonde
– MA6, MA3, IS, SM Bridge, MA1 + Sonde

Process Algal samples upon return – 3 Samples from MA6

LL Downloaded all 3 x Barologger – 3 ok records available

Note: Water level high just after 2 days of rain – visual of ~ 6" rise @ IS
Calm water + wind, clearish water relatively flat

@ 2030hrs complete algal sample initial processing

Bathy Meeting 19 MAY 15

CHUCK, BRANDON, TANNER

6:40 LEAVE SSC PACIFIC

7:44 ARRIVE AT SMB

GR BOAT LAST SESSION 35

SESSION 36 TODAY FOR CHECK

DISCONNECT

COLLECT

AUXILIARY POWER

BLUETOOTH CONNECTIVITY (COMM 5)

MAKE SURE TRANSMITTER IS ON

PILOT HOUSE IN OFF POSITION

TURN ON MAIN POWER

5/20 ~0900 Start Session 37

Bathy transects up to top of estuary (start w of ~SMB)

~1032 @ MAB - Stretch legs

Lose GPS when transiting under bridges

Top of estuary - did circle around large island (+ clockwise

Return trip to Bridge - RUN along shore, cross, then run along shore

went usually within 1 m of shore except brushes / vegetation.

Note: closed estuary has very high level our shoreline transects probably would be at edge of normal high tide condition.

Battery run ~ 9:10 - 11:45 ~2½ hrs

Put battery on charge using inverter & marine battery

After 3½ hrs - lights were 2 green 1 red

~1315 Session 38 & headed west to I5 North & South

GPS lost below bridges - attempted to go straight thru the interpolations

After I5 run south shoreline slow - background low, battery @ 11.8 v (on-50)
Same as before - good position for normal high tide condition
Went into + out of some side channels that probably fill only @ high tide
Complete @ 1545

☆ Remainder to do I5 Bridge west

Battery 1 Session 37: 15:57:28 – 19:15:19 (3:18) Clock Δ = 7 hrs to LOCAL
Battery 2 38: 20:15:19 – 22:52:52 (2:37) Δ = 7 hrs

Bathymetry II 20 MAY 16

Chuck Jennifer Edward

6:43 Depart SSC Pacific

7:45 Arrive SMB & request access permission

9:05 Access permission provided

9:20 Arrive IS

Start w/ Bathy Pod 2 in Z boat

0856 Z Boat on Start of couple cross sections west of bridge

Do shoreline mapping along south shore

Mapped inlet on south shore that is much longer than normal because of water level

Mapped in & around small islands but not all - maybe the major ones

Start Transect across on "western" south western shore of closed mouth

Pretty shallow in most of area

Work transects N/S from Estero to where depth was too shallow ~1/8 way across

Work the transects until depth allowed us to cross all the way to other side

Work transects N/S on North shore to where depths too shallow to cross

Only ~ 1/10 way across possible - R this until we can transit all the way across

~~Mapped N/S~~

~1140 changed batteries on boat & RC Controller on north shore near to previous exit of estuary to ocean

~1150 Starting on new batteries

Map N/S across whole estuary - hard to judge

~1315 RC Transmitter failed ~~and~~ pretty quickly - need to check into it

~~Back~~ Back to IS to meet up w/ Kyle & get new RC battery

1500 – Back in to water for final N/S sections just west of bridge
Some under it though GPS lost under there
1533 End transects – land on last legs of power
1600 Pick up
1645 depart

Session 39 S 15:56:02 = 8:56:02 — } 2:45
E 18:41:44 = 11:41:44 }

Troll 9500 SN 50440 CB 27July15

Sensor was removed from upper estuary 23July15. only 3 days of data was saved. Measuring Troll 9500 before cleaning and with no calibration, then will do a second measurement after cleaning. Salinity is measured using sea water off of the Pier at SDB.

13:50 measurements before cleaning:

pH 4.0 : 3.82 SDB Seawater: 35.45 psu
pH 7.0 : 78.14 100% DO : 107.8 % DO
pH 10.0 : 282.63 DI water: 0.10

- pH units for 7 : 10 changed
- pH 7 reading never stabilized
- pH 10 reading never stabilized
- Will only measure RDO % Saturation

16:00 measurements after cleaning:

pH 4.0 : 3.75 SDB seawater : 34.60 PSU salinity
pH ~~7~~.0 : 252.17 DI water : 0.36 PSU Salinity
pH 10.0 : 282.44 100% DO : ~~108~~ 107.9 % DO

- Above pH 4 units change and pH largely fluctuates
- DO fluctuated between 107.9% 108.2 %
