20. ABSTRACT (Continue on reverse side if necessary and identify by block number) The measurements of gravity acceleration described in the report were performed in 1977 within a grant program sponsored by the US Air Force. The introductory part of the report illustrates the transportable absolute gravimeter and ancillary instrumentation used in measurements, and describes the measurement method applied; uncertainty and errors are analysed as well. Measurements of gravity acceleration made in Europe prior to the USA program are also briefly considered before a detailed account is given of the measurements made in the USA. The numerous tables in the text and at the end of the report form an essential part		

UNCLASSIFIED

SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

of it. Six stations were observed in the USA and approximately 100 measurements made per station. The results show an overall uncertainty in g measurements of the order of $10 \mu\text{Gal}$.

SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

The work described in this final report was developed in the framework of an international grant programme for basic research of the US Air Force Office of Scientific Research, grant n° AFOSR 78-3529.

For the realization of the programme contributions were given by

- Italy : A. Bray, contractor representative, Director of the Istituto di Metrologia "G. Colonnetti" (IMGC), Torino; G. Cerutti, physicist, main investigator, researcher at IMGC; I. Marson, physicist, principal investigator, assistant professor at the University of Trieste; F. Alasia, higher-grade technician at IMGC.
- U.S.A. : B. Szabo, programme manager, Senior Scientist at the Terrestrial Science Division, Air Force Geophysical Laboratory (AFGL), Hanscom AF Base; W. Spita, gravimetrist, Geodetic Survey Squadron, DMATC, Warren AFB, Wyoming; J. Hammond, physicist, Geodesy & Gravity Branch, Terrestrial Sciences Division AFGL.

Measurements in USA were carried out by I. Marson, F. Alasia, W. Spita. G. Cerutti gave his cooperation also in preparing the report.

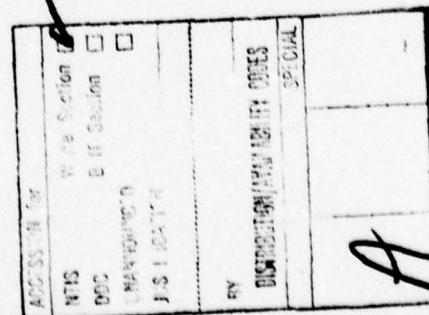

The Istituto di Metrologia "G. Colonnetti" of the National Research Council of Italy, developed, in cooperation with the Bureau International des Poids et Mesures (BIPM), Sèvres, a new transportable absolute gravity meter, with $10 \mu\text{Gal}$ uncertainty. This instrument was used in the past two years to determine the gravity acceleration in 17 European sites to improve the International Gravity Standardization Net (IGSN 71). (*)

In Autumn 1977 measurements were carried out in six sites in the United States : Bedford, MASS; Denver, COLO; Bismark, ND; Alamogordo, NM; San Francisco, CAL; Miami, FLA.

The work was supported by the US Air Force Geophysical Laboratory, Hanscom AFB, Bedford, Mass, under grant n° AFOSR 78-3529.

(*) Cerutti,G.; Cannizzo,L.; Sakuma,A. and Hostache,J.: "A transportable apparatus for absolute gravity measurements". VDI-Berichte n. 212, p. 49-51 (1974).

Cannizzo,L.; Cerutti,G.; Marson,I. : "Absolute gravity measurements in Europe", to appear shortly in Il Nuovo Cimento.

Symbols and Abbreviations

g	value of gravity acceleration (*)
g_{corr}	value of g corrected for tide effect
g_f	final mean value of gravity acceleration at height h from pillar surface, normalized at a reference fringe number and corrected for electronic delay
g_r	gravity value reduced to reference level (floor or pillar surface)
h	height from ground or pillar surface of the point where g is determined
h_{onk}	Honkasalo's corrective term
m	standard deviation
M	standard error
N	number of interference fringes in the trajectory of projected body
N_m	total number of g measurements at each station
N_r	number of reference fringes
t	time interval between the two passages across the higher station during one trajectory
T	time interval between the two passages across the lower station during one trajectory
T.C.	Earth tides correction
U.Time	Greenwich mean time (Universal Time)

(*) The value of g is given by the formula

$$g = \frac{4 \lambda (N - 0.25)}{T^2 - t^2}$$

where $\lambda = 0.632\ 991\ 4156\ \mu m$ is the wavelength of the He-Ne laser beam.

1. THE IMGC ABSOLUTE GRAVITY METER

1.1. Measurement method

The method adopted consists of the observation of the symmetrical free fall of a body in the gravitational field of the earth.

The advantages of this method are well known: relative freedom from residual air resistance and higher accuracy in time measurements, owing to the symmetry of the motion.

An object is projected vertically upwards and, in its rise and fall, it crosses twice two stations separated by distance L, whose value is accurately determined.

Two time intervals, T and t, corresponding to the two passages across the lower and upper stations respectively, are measured. The value of the acceleration due to the gravity force of the earth is given by

$$g = 8L/(T^2 - t^2) \quad (1)$$

The vertical gradient of the gravity force being assumed as constant along the whole trajectory, the value of g obtained from (1) corresponds to a point situated at height

$$z = L/6 + 1/3 \Delta H/6 \quad (2)$$

from the apex of the trajectory downwards (Δ is the distance between the apex and the upper station and is negligible with respect to L). The repeatability of the trajectory at each station and the determination of the apex are obtained with an uncertainty lower than 1 mm.

1.2. Technical description

The essential parts of the apparatus are a Michelson interferometer and a long-period seismometer (~ 20 s) (Figure 1). On the inertial mass of the seismometer is placed a corner cube (cc1) forming one mirror of the interferometer and the reference fixed point. The radiation from a stabilized HeNe laser is used. A second corner cube (cc2) is projected vertically in a vacuum cylinder (~ 0.1 Pa) and forms the movable mirror of the interferometer. Two photodetectors (Ph a, Ph b) detect the interference fringes during the vertical motion of the corner cube and drive the electronic counters of the flight time and the trajectory length.

1.3. Measurement techniques

No physical standard of length is used, therefore measurements

start at a pre-determined but arbitrary instant on the upward trajectory. At that point, fringe counting begins by means of a bi-directional counter guided by the signals of two photomultipliers. Simultaneously, computation of the total flight time begins as well. Another time counter is reset by each fringe in the rise and is stopped only by the first fringe in the fall motion, owing to phase relation inversion of the photodetector signals at the apex of the trajectory. This time interval is quantity "t" in eq. (1).

The upper station is therefore placed at the last fringe in the upward motion. If N is the total number of fringes recorded in the upward motion and λ the wavelength of the laser radiation, then

$$L = N \frac{\lambda}{2} \quad (3)$$

In the downward motion the counter counts the number of fringes in decreasing order, and when it reaches fringe 0, it stops counting of time T .

1.4. Errors

a) Distance measurement

It is directly connected with the measurement of the value of the laser light wavelength and with its stability. A maximum relative error of 5×10^{-9} , corresponding to $\pm 5 \mu\text{Gal}$, is expected.

Therefore, the laser wavelength is measured before and after each measurement trip. The use of a stabilized iodine laser of IMGC is planned.

Microseisms influence the determination of distance, as they alter the position of the fixed mirror.

These effects have been reduced by ~20 times by placing the fixed corner cube on the inertial mass of the seismometer.

The mechanical shocks of the catapult on the movable corner cube can be a source of disturbance for the experiment; for this reason, measurements begin with a pre-determined delay with respect to the STARTING POINT in order to avoid vibration of the corner cube.

b) Laser beam verticality

Verticality is obtained using a mercury pool. The error must be less than 10^{-4} rad in order that errors in "g" measurements can be less than $5 \mu\text{Gal}$. No correction was applied to the g value for this error, but a $\pm 5 \mu\text{Gal}$ uncertainty was introduced in the overall evalua-

tion of measurement uncertainty.

c) Trajectory verticality

Deviation from verticality must be less than 10^{-4} rad over the whole trajectory, to obtain homogeneous visibility (> 80%).

d) Movable corner cube rotation

Rotations must be less than 0.03 rad/s. The corner cube must be adjusted so that the optical and gravity centres coincide within 0.1 mm.

e) Time determination

A rubidium time standard is used, with 10^{-10} stability approximately. A Hewlett-Packard counter, with ± 1 ns resolution is used to determine time T. The "start" and "stop" pulses, obtained from the fringe counter, are affected by the delay-time of the circuits used, which introduce a systematic error in the determination of T of 10 ns ± 0.5 ns. In total, the uncertainty in T measurements is of ± 1.5 ns corresponding to approximately $\pm 6 \mu\text{Gal}$ in g determination (see Table D). The error in the determination of t is much higher, owing to the fact that a counter with ± 100 ns resolution is used.

Yet, being

$$t \ll T$$

the error on t becomes negligible.

f) Other influence factors

The presence of magnetic fields induce electrical currents in the metal of the corner cube during flight. To avoid this effect, all the metallic parts are made of amagnetic material.

The elastic of the catapult may have an electrostatic charge, and the movable corner cube may be charged by residual air. The elastic is therefore protected by a grounded metallic tube.

Moreover, if the trajectory is vertical, the tube is perfectly centred with respect to the corner cube, so that the capacitance between them keeps constant during flight and its effect is negligible.

No corrections were made for buoyancy or for reduction of the wavelength of the laser light caused by residual air.

g) The measured g value corresponds to a height of ~ 0.8 m from the ground. To reduce it to this level, the vertical gradient of g has to be measured, and a correction applied. To do this, a relative

gravimeter, type La Coste-Ramberg D-17, was used (W. Spita, operator). The results obtained at the individual stations, together with their measurement uncertainties, are given below. Δh represents the difference in the heights at which the Δg gravity difference was measured.

Vertical gradient of g at the different stations

Site	$\Delta h(m)$	$\Delta g(\mu\text{Gal})$	$\Delta g/\Delta h (\mu\text{Gal}/m)$
Bedford	.677 \pm .001	205 \pm 2	302 \pm 2
Denver	.830 \pm .001	244 \pm 2	294 \pm 2
Bismark	.821 \pm .001	209 \pm 2	255 \pm 2
Alamogordo	.829 \pm .001	244 \pm 4	296 \pm 5
San Francisco	.829 \pm .001	258 \pm 3	311 \pm 4
Miami	.855 \pm .001	260 \pm 3	304 \pm 4

A typical example of the evaluation of errors is given below, as well as their overall evaluation.

Source of error	Estimated uncertainty (μGal)
1) Laser wavelength	\pm 5
2) Beam direction	\pm 5
3) Time interval T (± 1.5 ns)	\pm 6
4) Gradient of g	\pm 2

The uncertainty in the g value is thus $\pm 10 \mu\text{Gal}$, calculated as the square root of the sum of the squares of the individual errors.

2. PREVIOUS MEASUREMENTS

As was said before, 17 European sites had been determined (Figure 2). The results will be published in a special number of the review "Il Nuovo Cimento" in the first months of 1978.

At this point it is interesting to see how the Italian apparatus agrees with Sakuma's absolute gravity meter and what is its repeatability (Table A, B).

3. U.S. MEASUREMENTS

From Oct. 5th to Dec. 5th 1977 the IMGC apparatus was used in the United States. The sites were chosen in order to give the highest contribution to the U.S. portion of the IGSN 71.

The stations are:

- 15221 A Boston : situated on Pier n° 1 in the building 1111 of the HANSCOM AFB, Bedford, Mass. (IGSN 71 point. Table E, N)
- 11994 H Denver : situated in room n° 13, Boettcher West, University of Denver, Colo. (Figure 10, Table F)
- 15560 A Bismark : in the basement of the Post Office building in Bismark, ND. (Figure 11, Table G)
- 11926 A Alamogordo : on the pier in room n° 10, building 1256, Hollomon AFB Alamogordo, NM. (Figure 12, Table H)
- 12172 A San Francisco: IGSN 71 point. (Table L)
- 08150 C Miami : situated on the U.S. Naval Observatory Time Service Substation, Astrolab building, Miami, FL. (Figure 13, Table M)

The microseism noise level was, usually, very high (amplitude $< 2 - 3 \mu\text{m}$ and frequent changes in frequency) except for the station in Boston (amplitude $< 1 \mu\text{m}$). The environment conditions in Miami caused some problems because of the temperature and the air currents of the air conditioning system.

The effects are standard deviations higher than the average ones in Europe, but still acceptable.

Tables C and 1 + 47 show the results of the measurements.

Figures 3 - 9 report the histograms of the recorded data.

TABLE A Comparison with Sakuma's value of "g" at Sèvres

Station, date	gr (μ Gal)	m (μ Gal)	M (μ Gal)
Sèvres A ₃ by Sakuma	980 925 900		
Sèvres, May 1976	980 925 892	20	2.0
Sèvres, June 1976	980 925 902	17	1.8
Sèvres, January 1977	980 925 896	19	2.1
Sèvres, March 1977 &	980 925 906	17	1.9

& Owing to the rainy weather, the water level of the Seine river was 4.5 m higher than the normal level. An increase in the g value is thus to be expected. This increase was estimated about 3 μ Gal by Dr. Sakuma.

TABLE B Repeatability of the measurements in the same station

Station, date	g_r (μ Gal)	m (μ Gal)	M (μ Gal)
Sèvres, May 1976	980 925 892	20	2.0
Sèvres, June 1976	980 925 902	17	1.8
