20. Abstract

Pursuant to Fublic Law 92-367, Phase I Inspection Reports are prepared under guidance contained in the recommended guidelines for safety inspection of dams, published by the Office of Chief of Engineers, Washington, D. C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general conditions of the dam is based upon available data and visual inspections. Detailed investigation and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

Based upon the field conditions at the time of the field inspection and all available engineering data, the Phase I report addresses the hydraulic, hydrologic, geologic, geotechnic, and structural aspects of the dam. The engineering techniques employed give a reasonably accurate assessment of the conditions of the dam. It should be realized that certain engineering aspects cannot be fully analyzed during a Phase I inspection. Assessment and remedial measures in the report include the requirements of additional indepth study when necessary.

Phase I reports include project information of the dam and appurtenances, all existing engineering data, operational procedures, hydraulic/hydrologic data of the watershed, dam stability, visual inspection report and an assessment including required remedial measures.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

Name of Dam:Falls MillsState:VirginiaCounty:TazewellUSGS Quadrangle Sheet:Bramwell, W. Va. - VirginiaStream:Mud Fork, Bluestone River

This dam is a 20-foot high, 445-foot long dam consisting of a 305-foot long ashlar masonry dam with a 140-foot earthen abutment. It has a 200-foot long uncontrolled overflow section which acts as the principal spillway. It has two 36-inch drain valves which are not operated. Based on the results of this inspection, the dam appears to require remedial measures due to deficiencies which could be hazardous depending on conditions. (See Appendix VI, Conditions)

The spillway capacity is inadequate and is not capable of passing one-half of the probable maximum flood (PMF) without overtopping of the earthen abutments. However, because of the vegetative growth, it is not likely that an overtopping of 0.7 feet for 6.0 hours during the one-half PMF occurrence will result in significant failure of the earth abutments. The spillway is capable of passing 35 percent of the PMF. It is recommended that during periods of unusually high runoff, the owner provide around-the-clock surveillance of the dam and have a warning system in the event of overtopping of the earth sections. The owner should make provisions in the future which would allow for safe passage of a larger flood at this site.

The masonry dam is apparently stable. However, adequate information is not available to evaluate its stability during the anticipated worst conditions of loading. Therefore, an investigation should be made within 6 months to determine the strength parameters of the dam masonry and the foundation rocks, and evaluate the factors of safety for stability of the dam. It is apparently not currently possible to operate the reservoir drains and lower the water level below the overflow elevation, because of sedimentation, and at least one of the valves should be made operable within the next year. There is excessive tree growth on the slopes of the abutments which should be removed and the slopes vegetated within 30 days. Because there is no program regular maintenance, it is recommended that one be prepared for this dam and its appurtenances within one year.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM NAME OF DAM: FALLS MILLS DAM I.D. NO.: VA 18503

SECTION I - PROJECT INFORMATION

1.1 General

1.1.1 <u>Authority</u>: Public Law 92-367, 8 August 1972, authorized the Secretary of the Army, through the U.S. Corps of Engineers, to initiate a national program of safety inspections of non-federal dams throughout the United States. The Norfolk District of the U.S. Corps of Engineers has been assigned the responsibility for supervising the inspection of dams in the Commonwealth of Virginia. Gilbert Associates, Inc. has entered into a contract with the Norfolk District to inspect this dam, Gilbert Work Order 06-7250-003.

1.1.2 <u>Purpose of Inspection</u>: The purpose is to conduct a Phase I inspection according to the <u>Recommended Guidelines for Safety Inspection</u> of Dams (Reference 1 of Appendix V) and contract requirements between Gilbert Associates, Inc. and the Corps of Engineers. The objectives are to expeditiously identify whether this dam apparently poses an immediate threat to human life or property and to recommend future studies and/or any obvious remedial actions that may be indicated by the inspection.

1.2 Project Description

1.2.1 Dam and Appurtenances: Falls Mills Dam is a 20-foot high, 445-foot long dam consisting of a 305-foot long ashlar masonry dam with a depressed 200-foot long principal spillway and a 140-foot long earthen fill abutment on its right side. The masonry portion contains two 36-inch diameter discharge pipes with gate valves.

1.2.2 <u>Location</u>: This dam is located about 0.7 miles west of Falls Mills, Virginia on the Mud Fork of the Bluestone River. See Location Map in Appendix I.

1.2.3 <u>Size Classification</u>: This dam is classified as a "small" structure based on its storage capacity of 990 acre-feet, in accordance with Section 2.1.1 of Reference 1 of Appendix V.

1.2.4 <u>Hazard Classification</u>: The dam is located upstream of a river valley. From the USGS quadrangle sheets, it appears that very few dwellings exist near the dam and it is therefore given a "significant" hazard classification in accordance with the guidelines contained in Section 2.1.2 of Reference 1 of Appendix V. The hazard classification used to

- 1 -

categorize dams is a function of location with respect to people and property only and has nothing to do with its stability or probability of failure.

1.2.5 <u>Ownership</u>: The dam is owned by the Falls Mills Fishing Club. The President of the Club is Dr. G. Prescott of Princeton, West Virginia.

1.2.6 <u>Purpose</u>: Recreation. (According to a local resident, Mr. Bill Dixon, the dam was originally constructed as a water supply for the Norfolk and Western Railroad (N&W) but was never used for that purpose.)

1.2.7 Design and Construction History: There is apparently no available recorded data on the design and construction of this dam except for the three drawings in Appendix I. Those drawings indicate that the design and construction were done by personnel of the N&W or under their direction. The drawings also indicate the construction was done in two stages with the original dam constructed in 1908-1909 by Walton and Company and later raised 5 feet about 1912.

1.2.8 <u>Normal Operational Procedure</u>: There is no operation procedure for this dam according to Dr. Prescott, and any excess runoff flows freely over the spillway of the dam. The valves do not appear to be in operable condition.

1.3 Pertinent Data

1.3.1 Drainage Areas: The current drainage area of this dam is 17.8 square miles measured on the current USGS 7-1/2 minute quadrangle maps.

1.3.2 <u>Discharge at Dam Site</u>: The maximum flood of record at the dam site is not known. The discharge of the ungated spillway with the pool level at the top of the masonry dam is 3590 c.f.s. and 10,430 c.f.s. with the pool at the top of the earth embankment.

1.3.3 <u>Dam and Reservoir Data</u>: Pertinent data on the dam and reservoir are shown in the following table:

Table 1.1 DAM AND RESERVOIR DATA

		Reservoir			
Item	The	Areas acres	Ca Acre feet	pacity(a) Watershed inch	Length miles
Cop of Earth Abutment	2,332.0	105	990 ^(b)	1.04	-
op of Masonry Dam	2,329.3	100	714 ^(b)	0.75	
Ingated Spillway Crest	2,325.75	93.3	371.0	0.39	1.0
Steam at Elevation of Dam	2,310.00±	0	0	0	0

Notes:

 (a) Reservoir capacity is gross, no consideration was given to loss of storage capacity due to sedimentation

(b) Extrapolated from two given points.

- 3 -

SECTION 2 - ENGINEERING DATA

2.1 <u>Design</u>: See drawings in Appendix I. No other data available.

2.2 <u>Construction</u>: Some material quantities and foundation conditions are given on the drawings in Appendix I. No other data are available.

2.3 Operation: There are no operational data.

2.4 <u>Evaluation</u>: The available information appears to be consistent with observed structures based on our visual inspection. There was no information on the materials or construction methods used for constructing the earth embankment on the right side of the dam. There is inadequate information available to evaluate this structure under all loading conditions.

SECTION 3 - VISUAL INSPECTION

3.1 Findings: This dam appears to be in good horizontal and vertical alignment. The masonry, including its joints, was apparently not significantly eroded. No significant downstream seepage was observed at either the masonry dam or its abutments; however, observations of some areas of the earthfill on the downstream right abutment were obstructed by the dense tree growth. The reservoir slopes were gentle and appeared to be stable.

There was excessive sedimentation in the reservoir to within about 2.6 feet of the spillway crest for its full length. The sediments were visible below water within about 5 feet (horizontally) of the spillway. The two 36-inch drain values did not appear to be operable because of the silt buildup in the reservoir.

There was excessive tree growth on the slopes of both abutments.

3.2 Evaluation: The dam appears to require some remedial measures. The masonry appears to be in very good condition but the earthen portions of the right and the left abutments have excessive tree growth. The exposed abutment on the left appears to consist of competent rock. The reservoir appears to contain a large amount of sediment.

SECTION 4 - OPERATIONAL PROCEDURE

4.1 <u>Procedures</u>: None. Neither drain value has been operated during recent history according to the owner's representative. Flow over the spillway is uncontrolled.

4.2 <u>Maintenance of Dam</u>: There are no maintenance records or program available for this dam.

4.3 <u>Maintenance of Operation Facilities</u>: None has been performed recently, according to the owner's representative.

4.4 <u>Warning System</u>: No formal warning system is in existence for this dam.

4.5 <u>Evaluation</u>: Periodic maintenance of the dam, including the earthen abutment, is not adequate. A warning system is recommended.

SECTION 5 - HYDRAULIC/HYDROLOGIC DATA

5.1 <u>Design</u>: Other than the attached drawings no design data are available.

5.2 Hydrologic Records: None are available.

5.3 Flood Experience: None is available.

5.4 Flood Potential: Various flood hydrographs were routed through the reservoir. Results are described in paragraph 5.6.

5.5 <u>Reservoir Regulation</u>: Currently there is none. The drain valves on either side of the spillway are not operated and the flow over the spillway is uncontrolled.

5.6 Overtopping Potential: The PMF, one-half the PMF, and the 100-year flood hydrographs were developed for the Falls Mills Reservoir drainage basin and routed through the reservoir. The following table summarizes the results of this procedure:

	Flood Hydrograph					
PMF	1/2 PMF	100-Year				
30,700 30,300	15,340 15,150	3,760 3,600				
2,335.7	2,332.9	2,329.3				
7.0 14.9	5.0 12.6	2.3 7.8				
4.5 12.1	2.4 8.6	:				
2.8 9.3 11.0	0.7 4.4 6.0	:				
-	-	-				
	PMF 30,700 30,300 2,335.7 7.0 14.9 4.5 12.1 2.8 9.3	PMF $1/2$ PMF 30,700 15,340 30,300 15,150 2,335.7 2,332.9 14.9 7.0 5.0 14.9 12.6 4.5 2.4 12.1 8.6 2.8 0.7 9.3 4.4				

Table 5.1 FALLS MILLS RESERVOIR FLOOD ROUTING

The hydrographs were developed and routed by using the HEC-1 computer program (Reference 5 of Appendix V) and appropriate precipitation, unit hydrograph, and storage volume versus outflow data as input. The triangular unit hydrograph was developed from the drainage area and estimated time to peak (Reference 2 of Appendix V). Probable maximum precipitation and 100year precipitation data were obtained from U.S. Weather Bureau publications (References 3 and 4 of Appendix V).

- 8 -

Information from record drawings was used to compute the storage-outflow relation. Losses were estimated at an initial loss of 1.0 inch and a constant loss rate of 0.30 inch/hour.

5.7 <u>Reservoir Emptying Potential</u>: The two 36-inch diameter gate valves, presently inoperative, would allow complete drawdown of the Falls Mills Reservoir if they were restored to operating condition.

Using those discharge pipes, it would take about 17 hours to drain water from the reservoir at a rate of about 342 c.f.s. at spillway crest elevation. The dam cannot now be emptied by the discharge pipes.

5.8 Evaluation: The results indicate that the Falls Mills spillway is not capable of passing one-half the PMF without overtopping the stone abutments and the earth abutment. However, it is not likely that 0.7 feet of overtopping resulting from one-half the PMF for 6.0 hours will result in significant failure of the embankment, based on the visual inspection. The 100-year flood raises the water surface up to the top of the stone abutments, which leaves approximately 3 feet of freeboard to the top of the earth abutment.

SECTION 6 - DAM STABILITY

6.1 <u>Stability Analysis</u>: No record of a previous stability analysis was available at the time of this inspection. As part of this report, a stability analysis was performed for this masonry dam. Some of the basic assumptions used for this analysis are indicated on the summary sheet in Appendix IV. The assumptions used included:

a. While a full horizontal hydrostatic load and silt load are used in computing overturning moments, only 50 percent of the hydrostatic head is used in computing uplift at the heel.

b. The design sediment level was 1 foot higher than measured during the inspection as an allowance for sedimentation buildup occurring over the next few years.

c. Tailwater forces were judged to be not significant.

d. Values for shear strength (2 KSF) and friction angle (37 degrees) at the masonry joint at elevation 2,310 feet are judgements.

6.2 <u>Foundation and Abutments</u>: The dam foundation consists of competent sandstone and blue slate (probably hard shale) rocks as given in the drawing, Appendix I. The rocks, as observed at the downstream toe, appeared to be strong and resistant to weathering.

The left abutment consists of sandstone and shale strata as shown on the drawing. The right abutment consists of the fill embankment resting on natural soil and rock strata (See drawings). The embankment slopes are 3 horizontal to 1 vertical and 2 horizontal to 1 vertical upstream and downstream, respectively. However, no information on the properties of the fill soils and the natural soils at the right abutment is available to evaluate the stability of the embankment.

6.3 <u>Evalution</u>: Based on historic performance and the field inspection, the stability of the dam, its foundation, and the left abutment appears to have been adequate for previous loading conditions. No evaluation could be made for the stability of the fill embankment at the right abutment because of lack of the requisite information. However, no significant distress of the embankment was observed during the field inspection.

Information on constituent embankment soils and their properties (namely, gradation, permeability, density, and shear strength) as well as

-10-

those of the underlying natural soils and the soft shale underlying the masonry dam should be obtained.

The stability calculations performed for the masonry dam indicate the factor of safety for sliding is less than that recommended in Reference 7 of Appendix V and the resultant of overturning forces does not lie within the middle third of the dam as recommended in Section 4.4.4.4 of Reference 7 of Appendix V. These recommendations are for concrete gravity dams, however, it is our opinion that similar guidelines should apply to masonry dams.

The dam is located within Zone 2 on the Algermissen Seismic Risk Map of the United States (1969 edition) and there are uncertainties with respect to the static stability of the dam, as described in paragraph 6.3. Therefore, in accordance with paragraph 3.6.4 of Reference 1 of Appendix V, assessments should be made regarding seismic stability, based on the studies outlined in paragraph 7.2.2.

SECTION 7 - ASSESSMENT, RECOMMENDATIONS/REMEDIAL MEASURES

The assessment, recommendations, and remedial measures contained in this report are based on the provisions of Appendix VI, Conditions.

7.1 Dam Assessment: On the basis of the field inspection, available drawings, and historic performance, the dam in its present condition does not show major and critical signs of distress such as displaced masonry units; severely eroded masonry joints; unanticipated settlement; or cracking, slope failures, or seepage at the abutments. However, several areas of concern regarding its future condition are:

7.1.1 The spillway capacity is inadequate in that the 140-foot long earthen abutment constructed of unknown materials will be overtopped by the one-half PMF. However, it is unlikely that overtopping for 6.0 hours will result in significant failure of earth abutments.

7.1.2 According to stability calculations performed, the ashlar masonry dam does not have an adequate factor of safety against either overturning or sliding.

7.1.3 The drain values did not appear to be operable and therefore cannot be used to lower the reservoir elevation below the spillway crest during emergency conditions.

7.1.4 There is excessive tree growth on the upstream and downstream slopes of the abutments.

7.1.5 There is no program for regular maintenance on this dam according to the owner's representative.

7.2 <u>Recommendations/Remedial Measures</u>: The following measures are recommended because of the previously stated concerns:

7.2.1 During periods of unusually high runoff, the owner should provide around-the-clock surveillance and have a warning system in the event of overtopping of the earthen sections. The owner should make provisions in the future which would allow for safe passage of a larger flood at this site.

7.2.2 A study should be made within 6 months to determine the properties of the fill embankment and its foundation soils, as well as the soft shale, the strength parameters of the critical masonry joint, and methods of providing an adequate factor of safety against sliding and overturning. The results of such a study should be implemented soon after the study. It is suggested that the urgency would be determined during the

- 12 -

study, but in any case, measures should be implemented to provide the required factors of safety within one year.

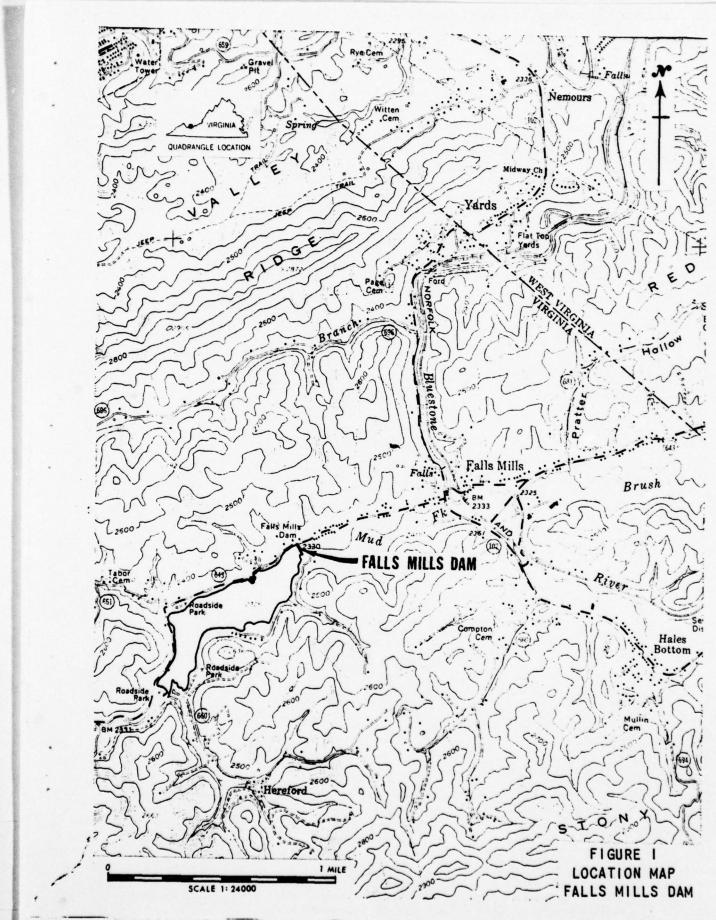

7.2.3 It is recommended that at least one of the drain values be made operable within the next year. It is suggested that because of the depth of sediment, the southerly drain value may be more effective in lowering the water level at the right abutment.

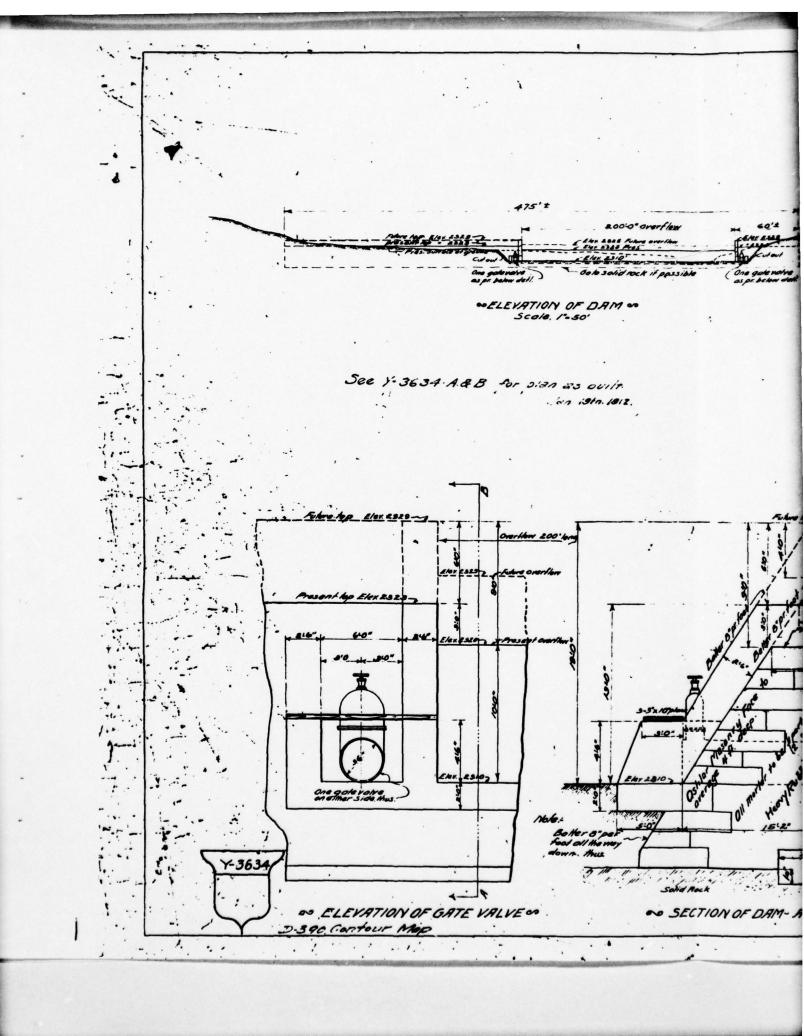

7.2.4 It is recommended that within 30 days the abutment slopes and the fill embankment be cleared of trees, grasses or other acceptable ground cover be established on the upstream and downstream slopes, and areas of disturbed riprap be repaired on the upstream slopes of the embankment.

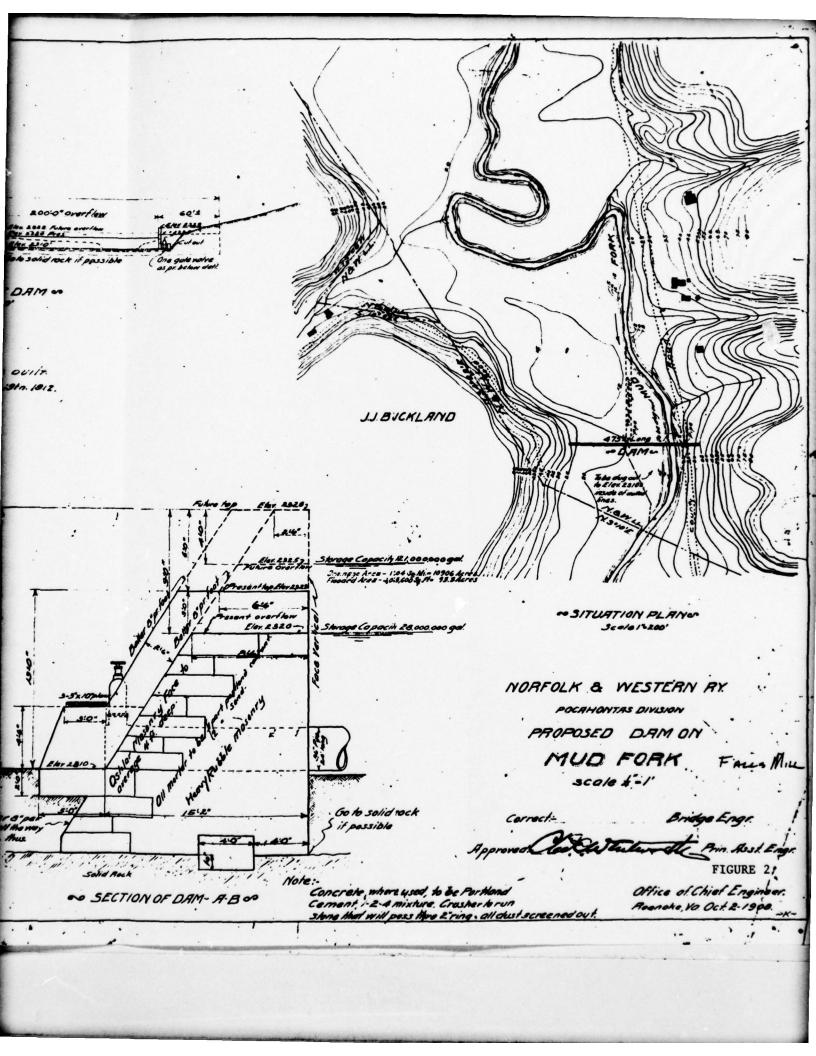

7.2.5 It is recommended that within one year a program for regular maintenance be developed for this dam and the program instigated soon thereafter.

CONCRETE/MASONRY DAMS

Sheet 1

	CNOT TUANTOO	CNOT TRANSPORT AND CONVERSION
SEEPAGE OR LEAKAGE	None observed at the dam-abutment junction at downstream left. No foundation underseepage was suspected. Because of dense vegetation, seepage at the dam- abutment at right or downstream of the fill embankment, if any, could not be seen. However, no significant seepage is suspected there. No leak through the dam was observed.	Heavy siltation of the reservoir in the vicinity of the dam may have reduced the seepage.
STRUCTURE TO ABUTMENT/EMBANKMENT JUNCTIONS	Except for some tree growth on the left abutment and heavy vegetative growth at the right abutment, the junctions showed no apparent signs of distress.	The trees at the left abutment should be removed. The vegetation on the right side must be cleared of trees and bushes.
DRAINS	None observed.	
WATER PASSAGES	Not applicable.	
FOUNDATION	No unusual foundation behavior is apparent. The exposed shale and sandstone rocks at the toe appeared hard and appeared to have good resistance to weathering.	None.

CONCRETE/MASONRY DAMS

Sheet 2

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECOMMENDATIONS
SURFACE CRACKS CONCRETE SURFACES	None visible.	None.
STRUCTURAL CRACKING	None visible.	None.
VERTICAL AND HORIZONTAL ALIGNMENT	Good	None.
STNIOL HTILONOM	None. The masonry joints did not appear to be significantly deteriorated.	
CONSTRUCTION JOINTS	None visible, but the joint made during the 1912 dam raising showed no signs of distress.	None.

	EMBANKMENT	Sheet 1
VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECOMMENDATIONS
SURFACE CRACKS	None observed. None visible on the downstream slope because of dense vegetation; none suspected.	The surface of the dam should be cleared of trees and large bushes to enable closer observation of its condition.
UNUSUAL MOVEMENT OR CRACKING AT OR BEYOND THE TOE	Apparently none.	See recommendation above.
SLOUGHING OR EROSION OF EMBANKMENT AND ABUTHENT SLOPES	None.	•
VERTICAL AND HORIZONTAL	Vertical and horizontal alignments could not be verified because of the vegetation.	None.
RIPRAP FAILURES	Some shoreline surface lining failure seen near the right abutment. A section of the shoreline protection appeared to consist of masonry units similar to those used in the dam construction.	Lining must be repaired.

	Sheet 2	REMARKS OR RECOMMENDATIONS	The area must be cleared of large bushes and trees for closer examination.	None.					
	EMBANKMENT	OBSERVATIONS	The junction with dam and natural ground were not properly visible for inspection because of vegetation.	None observed; but, significant seepage is not suspected because a significant flow of water was not noticed going to the downstream channel from the abutment areas.	None.	None visible.			
•		VISUAL EXAMINATION OF	JUNCTION OF EMBANKMENT AND ABUTMENT, SPILLMAY AND DAM	ANY NOTICEABLE SEEPAGE	STAFF GAGE AND RECORDER	DRAINS			

INTAKE STRUCTURE None.

111-6

. a

Two 36-inch gate valves, one on either side of the spillway, are presently inoperative.

None.

OUTLET CHANNEL

EMERGENCY GATE

At least one should be made operable to provide for reservoir drawdown.

UNGATED SPILLWAY Sheet 1	OBSERVATIONS REMARKS OR RECOMMENDATIONS	The ashlar masonry weir was apparently in good condition.	Silted to within 2-1/2 feet of the crest None. of the spillway.	Rocky and wooded. Slopes are stable. None. Silty deposits on rocks and trees and erosion of lower 3 to 4 feet of slope areas indicated recent tailwater buildup possibly resulting partially from a bridge several hundred feet downstream.	None across the spillway. None.	
	0	The as in goo	Silted of the	Rocky Silty erosio areas possib severa	None a

REMARKS OR RECOMMENDATIONS

VISUAL EXAMINATION OF	OBSERVATIONS	
MONUMENTATION/SURVEYS	None observed.	
OBSERVATION WELLS	None.	
WEIRS	None.	
PIEZOMETERS	None observed.	
OTHER	None observed.	

•	Sheet 1	REMARKS OR RECOMMENDATIONS	None.	Sediments are blocking the 36-inch drain pipes, and increasing the horizontal loading on the dam.
•	RESERVOIR	OBSERVATIONS	Densely wooded without any visible exposed areas.	Observations from the shoreline and the the dam indicated there is heavy siltation to within 2.6 feet of the overflow elevation.
•		VISUAL EXAMINATION OF	SLOPES	SEDIMENTATION

DOMNSTREAM CHANN VISUAL EXAMINATION OF OBSERVATIONS VISUAL EXAMINATION OF OBSERVATIONS COMDITION Some fallen trees, rock pieces, rock pieces, of the dam. CONDITION Some fallen trees, rock pieces, rock pieces, bridge approximately 200 feet dam. CONDITION Some fallen trees, rock pieces, rock pieces, rock pieces, bridge approximately 200 feet dam. SERRIS, ETC.) Some fallen trees, rock pieces, rock pieces, bridge approximately 200 feet dam. SIOPES Rocky, tree covered and stable trees failures. APPROXIMATE NO. OF The 1962 Branwell, W. Va Va. APROXIMATE NO. OF The 1962 Branwell, W. Va Va. APROXIMATE NO. OF The 1962 Branwell, W. Va Va. APROXIMATE NO. OF The 1962 Branwell, W. Va Va. APRES AND POPULATION Indicates Branwell, W. Va Va. Blam and Where the stream enters Blam and to a population of al 36 people.	Sheet 1 REMARKS OR RECOMMENDATIONS None. None.	
	DOWNSTREAM CHANNEL DOWNSTREAM CHANNEL <u>OBSERVATIONS</u> Some fallen trees, rock pieces, a small bridge approximately 200 feet downstream of the dam. Rocky, tree covered and stable with regard to large failures. Rocky, tree covered and stable with regard to large failures. The 1962 Bramwell, W. Va Va. quadrangle indicates nine buildings (including a church) below contour 2320 between the dam and where the stream enters the Bluestone River. This would correspond to a population of about 36 people.

TAXES IN

APPENDIX VI

CONDITIONS

This Report is based on a visual inspection of the dam, a review of available engineering data, and a hydrologic analysis performed during a Phase I investigation as set forth in the U.S. Corps of Engineers' <u>Recommended Guidelines for Safety Inspection of Dams</u> and the contract between the U.S. Corps of Engineers and Gilbert Associates, Inc.

The foregoing inspection, review, and analysis are by their nature limited in scope. It is possible that conditions exist which are hazardous, or which might in time develop into safety hazards, that are not detectable by this inspection, review, and analysis. Accordingly, Gilbert Associates, Inc. cannot and does not warrant or represent that conditions which are hazardous, or which may in time develop into safety hazards, do not exist.
