DEPARTMENT OF THE ARMY U. S. ARMY ENGINEER DISTRICT, NEW YORK 26 FEDERAL PLAZA NEW YORK, NEW YORK 10007

2 CCT 1978

NANEN-F

Honorable Hugh L. Carey Governor of New York Albany, New York 12224

Dear Governor Carey:

The purpose of this letter is to inform you of a clarification of the guidelines used by this office in assessing dams under the National Program of Inspection of Dams.

Office of the Chief of Engineers has recently provided a clarification that dams with seriously inadequate spillways are to be assessed as unsafe, non-emergency, until more detailed studies prove otherwise or corrective measures are completed.

The following dams in your state have previously been assessed as having seriously inadequate spillways, with capability to pass safely only the percentage of the probable maximum flood as noted in each report. They are now to be assessed as unsafe:

I.D. NO.	NAME OF DAM
N.Y. 59	Lowe: Warwick Reservoir Dam
N.Y. 4	Salisbury Mills Dam
N.Y. 45	Amawalk Dam
N.Y. 418	Jamesville Dam
N.Y. 685	Colliersville Dam
N.Y. 6	Delta Dam
N.Y. 421	Oneida City Dam
N.Y. 39	Croton Falls Dam
N.Y. 509	Chadwick Dam (Plattenkill)
N.Y. 66	Boyds Corner Dam
N.Y. 397	Cranberry Lake Dam
N.Y. 708	Seneca Falls Dam
N.Y. 332	Lake Sebago Dam
N.Y. 338	Indian Brook Dam
N.Y. 33	Lower(S) Wiccopee Dam (Lower Hudson W.S. for Peekskill)

NANEN-F Honorable Hugh L. Carey

I.D. NO.	NAME OF DAM
N.Y. 49	Pocantico Dam
N.Y. 445	Attica Dam
N.Y. 658	Cork Center Dam
N.Y. 153	Jackson Creek Dam
N.Y. 172	Lake Algonquin Dam
N.Y. 318	Sixth Lake Dam
N.Y. 13	Butlet Storage Dam
N.Y. 90	Putnam Lake (Bog Brook Dam)
N.Y. 166	Pecks Lake Dam
N.Y. 674	Bradford Dam
N.Y. 75	Sturgeon Pool Dam
N.Y. 414	Skaneateles Dam
N.Y. 155	Indian Lake Dam
N.Y. 472	Newton Falls Dam
N.Y. 362	Buckhorn Lake Dam

The classification of "unsafe" applied to a dam because of a seriously inadequate spillway is not meant to connote the same degree of emergency as
would be associated with an "unsafe" classification applied for a structural
deficiency. It does mean, however, that based on an initial screening, and
preliminary computations, there appears to be a serious deficiency in spillway capacity so that if a severe storm were to occur, overtopping and failure
of the dam would take place, significantly increasing the hazard to loss of
life downstream from the dam.

Consequently, it is advisable to implement the recommendations previously furnished in the reports for the above-mentioned dams as soon as practicable.

It is requested that owners of these dams be furnished a copy of this letter and that copies be permanently appended to all reports previously furnished to you.

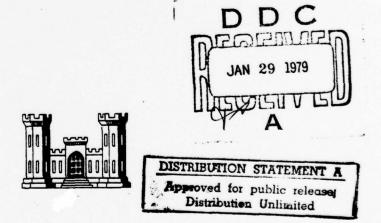

Sincerely yours,

CLARK H. BENN Colonel, Corps of Engineers District Engineer

This report provides information and analysis on the physical condition of the dam as of the report date. Information and analysis are based on visual inspection of the dam by the performing organization.

Lower Warwick Reservoir Dam was judged to be unsafe, non-emergency due to a seriously inadequate spillway.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

LOWER WARWICK RESERVOIR DAM
NEW YORK STATE
ORANGE COUNTY
WALLKILL RIVER BASIN
INSPECTED 9 AUGUST 1978

ASSESSMENT OF GENERAL CONDITIONS

The visual inspection and evaluation of Warwick Dam and its spillway did not reveal conditions which are considered to be unsafe at the present time.

The following non-emergency measures should be implemented prior to the spring season of 1979:

- 1. The vegetation and debris on the downstream westerly portion of the embankment should be cleared and inspected by a licensed Professional Engineer. The extent of the root systems of large trees should be evaluated prior to indiscriminant cutting.
- 2. A drainage ditch to collect surface runoff should be constructed on the downstream embankment slope where runoff in presently eroding the slope.
- 3. Toe drainage facility should be inspected and flow noted at frequent intervals.
- 4. A piezometer should be installed in the embankment and read periodically to evaluate changes in water level within the embankment.

The hydrologic analysis indicates that the spillway is capable of passing approximately 20 percent of the Probable Maximum Flood. Since the spillway is not capable of passing the Standard Project Flood, considered as one-half the Probable Maximum Flood, without overtopping the earth embankment and possibly causing failure, the spillway is therefore considered to be seriously inadequate in accordance with Corps of Engineers Screening Criteria. The hydrologic aspects of the dam should be further investigated and the Probable Maximum Flood computations refined. In the interim around the clock surveil-lance should be provided during periods of high flow, and a contingency plan initiated for implementation in the event of overtopping.

PHASE I INSPECTION REPORT NATIONAL DAM INSPECTION PROGRAM LOWER WARWICK RESERVOIR DAM I.D. NO. 59

SECTION 1 - PROJECT INFORMATION

1.1 GENERAL:

- a. Authority. Authority for this report is provided by the National Dam Inspection Act, Public Law 92-367, 1972.
- b. <u>Purpose of Inspection</u>. The purpose of this report and inspection is to identify deficiencies and hazardous conditions; determine if they constitute hazards to human life or property; make recommendations for remedial measures where necessary and thus permit correction in a timely manner by non-Federal interests.

1.2 DESCRIPTION OF PROJECT:

- a. Description of Dam. The Lower Warwick Reservoir Dam was built in approximately 1887 to supply water to the Village of Warwick, New York. It is the lowest of a system of three reservoirs used for the water supply of the Village. The dam is 210 feet in length; 185 feet being earth embankment possibly with a concrete core wall, and a 25 feet concrete gravity uncontrolled spillway. The dam crest is 3.3 feet above the spillway sill elevation of 679.8. The dam as originally constructed has a berm width of 12 feet and upstream and downstream slopes la horizontal on 1 vertical. A 20 inch cast iron pipe serves as the outlet works for the reservoir. It runs through the embankment just west of center and terminates in the downstream channel at invert elevation 651.12. The outlet pipe is controlled by a manual gate valve at the downstream toe of the dam. The lower dam forms the most downstream impoundment of a pumped storage system, supplying water to the Village of Warwick. Water is pumped via an eight inch diameter cast iron pipe; an offshoot from the 20 inch outlet pipe; to the upper reservoir for eventual distribution, by gravity, to the village.
- b. <u>Location</u>. The Lower Warwick Reservoir Dam, I.D. No. 59, is located approximately 1½ miles above the Village of Warwick, Orange County, New York. The latitude is 41°-14.1' and the longitude is 74°-21.7'.
- c. <u>Size Classification</u>. The available storage is approximately 12 million gallons or 36.8 acre feet at normal pool elevation (crest of spillway) with a pool area of 3.4 acres. The crest of the dam is approximately 25 feet above the existing grade. Based upon the above the dam is classified as small.
- d. <u>Hazard Classification</u>. The dam is classified as Hazard Category I based upon floodwave analysis and the proximity of downstream habitable development.
- e. $\underline{\text{Ownership}}$. The Lower Warwick Reservoir Dam is owned by the Village of Warwick.
- f. <u>Purpose of Dam</u>. The Lower Warwick Reservoir Dam forms the lowest of three reservoirs supplying water to the Village of Warwick. Water released from the lower reservoir is pumped to the highest of the three reservoir systems for eventual release to consumers in the village via gravity flow.

- g. <u>Design and Construction History</u>. The dam was constructed in 1887. Design data, plans, and construction information are not available.
- h. $\underline{\text{Normal Operating Procedures}}$. Formal operating procedures are not available.

1.3 PERTINENT DATA:

i. Regulating Outlets - There is a 20 inch outlet pipe at elevation 651.12 feet M.S.L. used for water supply.

SECTION 2 - ENGINEERING DATA

2.1 DESIGN:

There is no original design information available. During December 1977 the New York District inspected the Lower Warwick Dam at the request of Mr. Carl Quackenbush, Supt. of Public Works for the Village of Warwick. The purpose of the inspection was to provide technical advice regarding seepage through the earth dam. Recommendations made by the New York District were implemented by the Village during the spring of 1978. Construction plans were prepared by Wehran Engineering of Middletown, New York and included the following items:

- a. Immediate drawdown of the impoundment.
- b. Clear the downstream slope of debris.
- c. Construct an inclined drainage system with appropriate filter on the downstream face.
- d. Line the upstream face with bentonite .

Construction plans are included as Appendix A of this report.

2.2 CONSTRUCTION:

Original construction records are not available for review.

2.3 OPERATION:

There are no formal records of operation or discharge available.

2.4 EVALUATION:

Detail information is not available, however, sufficient information is available for a Phase I investigation.

SECTION 3 - VISUAL INSPECTION

3.1 FINDINGS:

a. <u>Background</u>. On 21 and 23 December 1977 representatives of the New York District, Corps of Engineers visited the Lower Warwick Reservoir Dam at the request of Mr. Carl Quackenbush, Supt. of Public Works for the Village of Warwick, to investigate thru seepage in the earth dam which had raised the concern of the village officials as to the integrity of the structure. The inspection was performed under the authority of Public Law 84-99 which authorizes the Corps of Engineers to lend technical assistance to non-federal public interests during emergency situations.

Visual observations at the time revealed thru seepage in the vicinity of the right abutment from approximately half-way down the downstream embankment slope to the base of the dam, seeping at several locations. Some piping was occurring at the seep locations and serious sloughing of the downstream face had occurred.

On 22 December 1977 the Supt. of Public Works, Village of Warwick was notified of a "potentially hazardous situation requiring immediate remedial action". On 23 December 1977 Governor Carey was notified of the distressed condition of the dam. On 6 January 1978 the State was advised to require the owner of the dam to take immediate action to: (a) drawdown the reservoir immediately (b) clear the downstream slope (c) construct an inclined drainage system on the downstream slope (d) provide a pipe weir at the drainage discharge (e) construct a stabilizing berm on the downstream slope (f) treat the upstream face with bentonite (g) install a piezometer on the embankment to monitor pore pressures.

Wehran Engineering of Middletown, New York, under contract to the Village of Warwick prepared a contract plan incorporating most of the above recommended actions. The work was completed during the spring of 1978 by Village personnel after approval of the plan by NYS DEC.

- b. <u>General</u>. The Lower Warwick Reservoir Dam was inspected by Corps of Engineers personnel on 9 August 1978 as part of the National Dam Inspection Program. At the time of the inspection water was spilling approximately two to three inches above the spillway crest. The weather was sunny with a temperature of approximately 90° F.
- c. Dam. The dam, built in approximately 1887, exhibited no signs of sloughing of the embankment slopes. The embankment and drainage system, constructed in the spring of 1978, as recommended by the New York District, was in excellent condition. A grass cover had been established on the new downstream embankment and the surface was well maintained. Surface drainage had eroded a shallow swale at the downstream embankment slope in the area of the eastern terminus of new construction. No evidence of seepage was noted on the downstream face and no water was evident in the toe drainage system. Numerous rock outcroppings were noted in the area, indicative of the earth section being founded on bedrock. It is questionable whether a concrete core wall, shown on an old drawing furnished by Mr. Quackenbush, actually exists. Areas of heavy bentonite concentrations were noted on the upstream slope, just below the water line. The abutment/embankment contact showed no evidence of distress.

Heavy growth on the entire western half of the downstream embankment slope prevented examination of this area. The above paragraph does not apply to this area.

- d. Spillway. The spillway, located at the west abutment is a concrete gravity section 25 feet in width. Two to three inches of water was flowing over the spillway at the time of inspection. The concrete appeared to be in good condition with minor surface scaling. There is no evidence of structural cracking. The spillway is cut into bedrock and the west abutment contact is in rock. No evidence of distress was evident.
- e. Outlet. A 20 inch cast iron outlet pipe extends through the embankment just west of the center of the dam. The outlet is controlled by a manual gate valve located in a valve pit at the downstream toe. The outlet control structure, located on the upstream embankment, and previously utilized to draw water from different levels, is not operable and is not utilized. The outlet pipe was extended upstream from the old control structure and presently draws water at elevation 659.6. The gate valve is maintained in a closed position except when drawdown of the reservoir is necessary. It is fully operational.
- f. Reservoir. There was no noticeable signs of sloughing or erosion in the reservoir area.
- g. <u>Downstream Channel</u>. The outlet channel is bedrock. A small amount of debris (tree limbs, etc.) was in the channel at the time of inspection.

3.2 EVALUATION OF OBSERVATIONS:

Visual observations did not reveal any conditions which would adversely affect the safety of the dam. However, the west downstream slope of the earth embankment could not be examined due to heavy growth and brush. The drainage collection system constructed on the downstream slope in the spring of 1978 is presently not passing any seepage, apparently due to the lining of the upstream face with bentonite.

SECTION 4 - OPERATION AND MAINTENANCE PROCEDURES

4.1 PROCEDURES:

The Lower Warwick Reservoir is the lowest of three reservoirs supplying water to the Village of Warwick. Water is normally discharged through the 20 inch cast iron outlet pipe, the gate valve at the downstream toe remaining in a closed position. The water is then pumped via an eight inch pipe to the upper reservoir for distribution to the village by gravity. The chlorination facilities are located just downstream from the lower dam.

4.2 MAINTENANCE OF DAM:

Heavy brush and growth on approximately one-half of the downstream slope made this area unaccessible. The remainder of the embankment and spillway are maintained in satisfactory condition by village personnel.

4.3 WARNING SYSTEM IN EFFECT:

No warning system is in effect.

4.4 EVALUATION:

Mr. Quackenbush, Supt. of Public Works for the Village of Warwick, informed the inspection team that the western half of the downstream slope will be cleared during the winter of 1978-79. The remainder of the dam is maintained in satisfactory condition.

SECTION 5: HYDROLOGY/HUDRAULIC

5.1 HYDROLOGIC EVALUATION OF FEATURES:

a. Design Data. Warwick Dam No. 1, is the most downstream dam of a series of three dams on a headwater tributary of Wawayanda Creek. Wawayanda Creek flows into Pochuck Creek, which is a tributary of the Wallkill River. The reservoirs formed by the dams are used for water supply for the village of Warwick. The dam is an earthen structure approximately 185 feet long and 25 feet high. The dam has a 24 foot concrete spillway cut out of rock and a 20 inch outlet pipe at its base for water supply.

Warwick Dam No. I was designed to function primarily as a water supply facility, not a flood detention structure. However, for the purpose of this investigation, the design features were analyzed with respect to their flood control potential. This potential was investigated through the application of the probable maximum flood (PMF) to the contributing basin. The PMF is that hypothetical flow induced by the most critical combination of precipitation, minimum infiltration losses, and concentration of run-off at a specific location, that is considered reasonably possible for a particular drainage area.

The contributing drainage area to the lower Warwick Dam is 1.3 square miles as shown on Appendix D. The main stream is relatively steep with an average slope of 350 feet per mile. Since this stream is typical of the fairly mountainous Appalachian Highlands, average Snyder parameters of 640 Cp = 400 and Ct = 2 were used for the determination of the unit hydrograph, the basic hydrologic working tool. Based on a Ct of , the lag time was developed as 2.7 hours. The lag time was increased by one hour to account for the time of travel through the system of three reservoirs for an estimated total lag time of 3.7 hours to the lowest reservoir site.

The probable maximum precipitation was developed through procedures in Hydrometeorological Report No. 33. The PMP index rainfall was determined to be 22 inches for a 24 hour storm duration over 200 square miles. The percentages of the index rainfall applied to other durations over the study basin were developed. Because of the critical nature of this storm, a fully saturated soil condition was assumed with minimum infiltration rates of 0.1 inch/hour. The peak discharge associated with the PMF as developed by the inclosed HEC I computer output is 1979 C.F.S. For purposes of this study, the standard project flood is taken as ½ the PMF or approximately 990 C.F.S.

The 24 foot spillway on the left bank of the dam was analyzed as a broad crested weir with a "C" coefficient of discharge of 2.65, using the formula $Q = CLH^{3/2}$. The maximum discharge capacity of the spillway with a head of 3.33 feet to the top of the dam was determined to be 386 C.F.S.

Based on a storage capacity of 12 million gallons, provided by Mr. Carl Quackenbush, the Warwick Supt. of Public Works, equivalent to 36.8 acre feet at spillway crest and a estimated surface area of 3.4 acres, a stage storage relationship was developed, as shown in Appendix $\underline{\mathsf{D}}$.

The lag time, Cp, drainage area, PMP index rain and percentages, loss rates and the reservoir storage versus discharge information was input into the HEC I program, "Flood Hydrograph Package". This program developed the unit hydrograph, the PMP rain data, applied the loss rates and developed the flood hydrograph. The PMF and a series of ratioed flood hydrographs were routed through the reservoir. An assumption of a full pool was made at the start of the routing. The technical computations are shown in Appendix D.

- b. Experience Data. Warwick Dam has been operational since approximately 1890. As far as can be determined, it has safely passed all floods which have occurred since it was built.
- c. <u>Visual Observations</u>. At the time of the on-site inspection, a few inches of water was flowing over the spillway, and there were no indications of any major problems.
- d. Overtopping Potential. As far as can be determined, no actual storm event has had sufficient magnitude and duration to overtop the dam since it was built. However, the hypothetical probable maximum and standard project floods would cause overtopping of this dam. It is estimated that the spillway is capable of passing only 20 percent of the Probable Maximum Flood.

5.2 HYDRAULIC EVALUATION OF FLOODWAVE:

- a. <u>General</u>. Since the lower Warwick Reservoir Dam is an earth embankment a condition of total failure was utilized in floodwave computations.
- b. The downstream channel was investigated on 23 December 1977. The resulting floowave analysis employed approximations as to stream cross-sections. The first critical location in the event of a dam failure is 3600 feet downstream from the dam, where there is a residential home development. At this location the resulting floodwave would overtop the stream banks by approximately 4 feet. At the most downstream location (8000 feet downstream from the dam, in the center of the village of Warwick) the resulting floodwave would be approximately one foot above stream bank elevation.
- c. It is considered that there is a potential for damage and loss of life caused by a failure of the dam and the resulting floodwave.

SECTION 6 - STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY:

- a. <u>Visual Observations</u>. Visual inspection of the lower Warwick Reservoir Dam did not reveal any areas which would represent a potential hazard due to instability. The western half of the earth embankment could not be inspected due to heavy brush growth on the downstream slope. The spillway is cut in rock and did not exhibit any serious signs of distress.
- b. <u>Design and Construction Data</u>. No design computations or other data regarding the structural stability of the dam or spillway are available.
- c. Operating Records. No major operational problems which would affect the stability of the dam or spillway were reported.
- d. <u>Post Construction Changes</u>. Repairs on the western portion of the downstream embankment slope were completed in the spring of 1978. The recently placed toe drainage facility is not passing water, indicative that the impervious blanket placed on the upstream slope in this area is functioning as anticipated.
- e. <u>Seismic Stability</u>. The dam is located in Seismic Zone No. 1, therefore no seismic analysis are warranted in accordance with Corps of Engineers guidelines.

SECTION 7 - ASSESSMENT/REMEDIAL MEASURES

7.1 DAM ASSESSMENT:

- a. <u>Safety</u>. The portion of the Lower Warwick Reservoir Dam, which was able to be inspected, did not exhibit any problems which would require an unsafe assessment. No evidence of seepage or unusual settlement was observed at the time of inspection, however, due to the presence of heavy brush growth, the entire western half of the embankment was neither observed nor inspected. Preliminary hydrologic evaluations performed indicate that the dam would be topped by the Standard Project Flood. It is estimated that the spillway is capable of passing 20 percent of the Probable Maximum Flood. Therefore, since the spillway is not capable of passing the Standard Project Flood, considered as one-half of the Probable Maximum Flood, without overtopping the dam and causing failure, it is considered to be seriously inadequate.
- b. Adequacy of Information. No reliable information was available regarding the dam section. This report is primarily based upon visual observations.
- c. Additional Investigations. Additional investigations to assess the safety of that portion of the dam and spillway observed are not necessary.

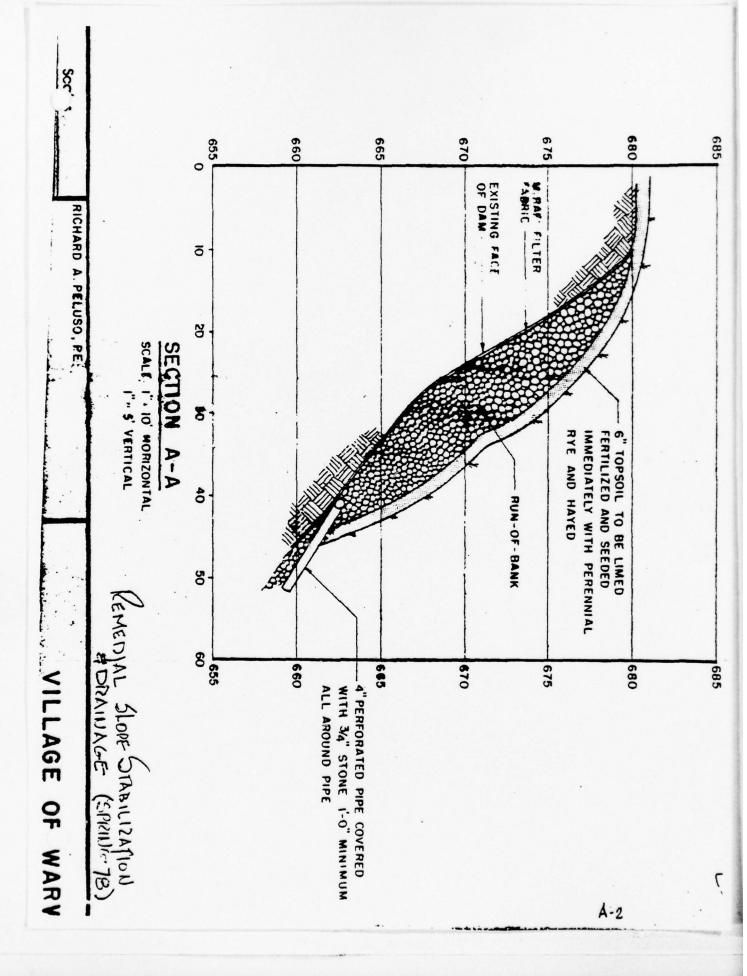

7.2 REMEDIAL MEASURES:

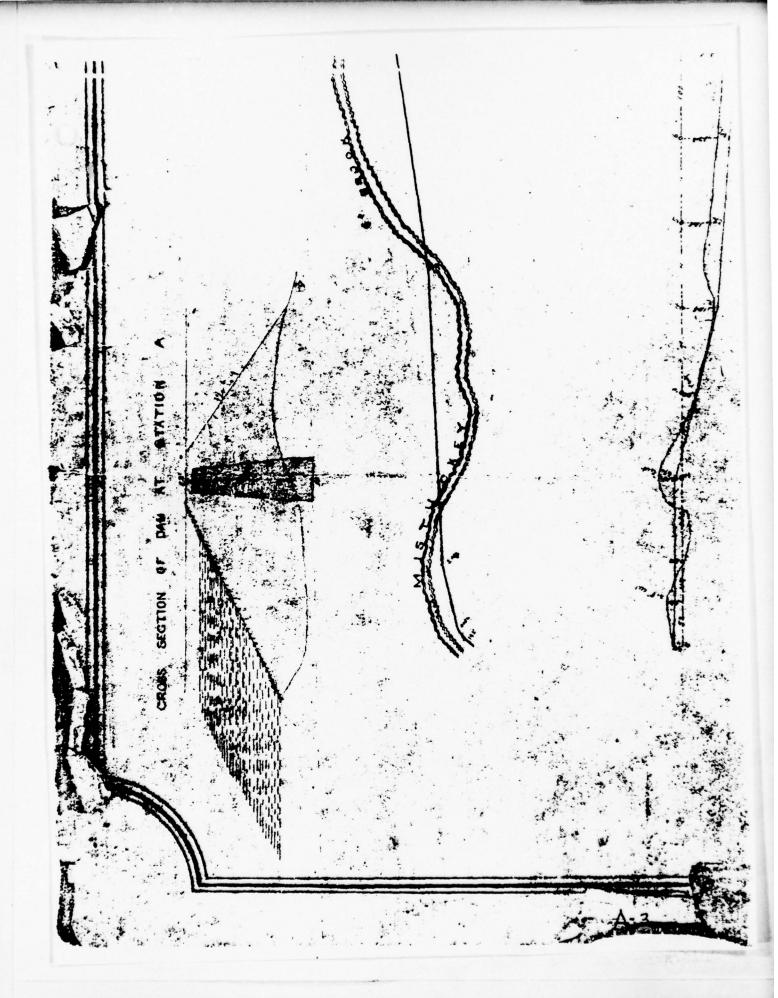

The following remedial measures should be accomplished prior to the spring of 1979:

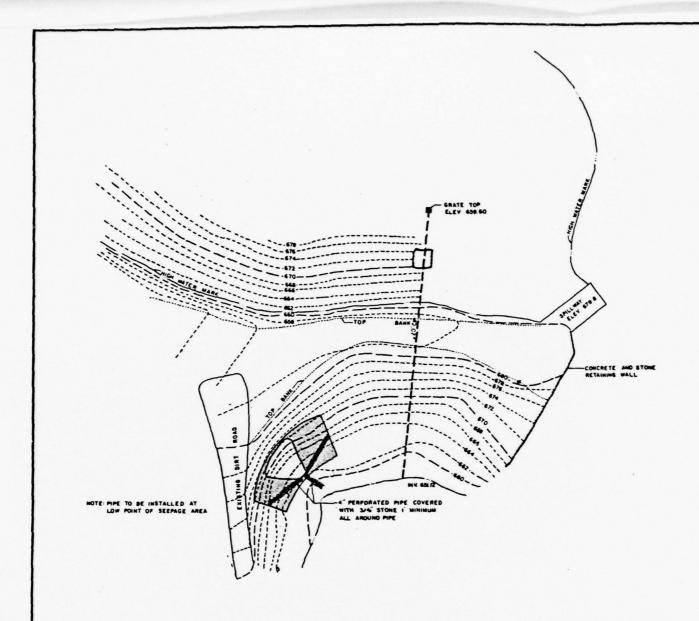

- The western half of the downstream embankment should be cleared of all vegetation and debris and inspected by a licensed professional engineer. The extent of the root system of large trees should be evaluated prior to indiscriminant cutting.
- 2. A drainage ditch to collect surface runoff should be constructed on the downstream slope in the area where runoff is eroding the downstream slope. A crushed gravel ditch lined with filter cloth should be provided.
- 3. A piezometer should be installed in the embankment and read periodically to evaluate water levels in the embankment soils.
- 4. The toe drainage facilities should be inspected and flow noted at weekly intervals.
- 5. During periods of high flows around-the-clock surveillance of the dam should be provided and a contigency plan should be initiated for implementation in the event of overtopping.

NADEN-TG
90 Church St.
New York, New York 10007

Dear Mr. Parrillo:

After my telephone conversation with you on November 15th, I was speaking with my water plant operator about our conversation. He asked if I had mentioned to you the leak we have in the dam of the lowest reservoir, which we have been aware of for the past couple of years. Why I didn't think to tell you of this during our conversation I can't explain. We have been involved in many different projects for the past few months and things have been somewhat heetic. I guess I was not thinking straight.

I thought I would make you aware of this by letter, in hopes you might be able to arrange for one of your personnel to look at this and inform us if there might be a temporary correction we might be able to make.

I am not sure which I.D number applies to this dam. Following are our I.D. numbers you gave me: #0059,#0062 and #0063.

Thanking you in advance.

Very truly yours,

Carl Quachenbush Supt. of Public Works

Dear Mr. Quackenbush:

On 21 December 1977 an on-site inspection of the lowest of the three (3) earth dams, inventory I.D. No. 59, Hazard Category 2, in the Village of Warwick, Orange Co., N.Y. was made at your request.

Visual observations revealed through seepage in the vicinity of the right abutment from approximately half-way down the slope which has caused considerable sloughing and softening of the downstream embankment. We consider this to be a potentially hazardous situation requiring immediate action to alleviate the condition. A copy of the above has been forwarded to the GCovernor of the State and the State regulating agency charged with dam safety.

Sincerely yours,

Caspe/nanen-f

Mr. Cari Quackenbush Supt. of Public Works Village of Warwick 77 Main St. Warwick, NY 10990

RE: Dam #397, Lower Hudson Basin

Dear Mr. Quackenbush:

Reference is made to the inspections of December 21, 1977 and December 23, 1977 of the lower earth dam in the Village of Warwick. The inspections were made by the NY District Corps of Engineers and New York State. Reference is also made to the letter of December 22, 1977 from the Corps of Engineers. This letter indicates that the seepage has caused considerable sloughing and softening of the downstream embankment. In order to remove the hazard to the downstream residents, the following remedial work should be performed immediately:

- 1. The water surface of the reservoir should be lowered below the seep.

 The seep appears about 6 feet below the existing water surface, therefore, the water surface should be lowered about 8 feet by opening the drain pipe.
- 2. At the time of the inspections, the trees and brush on the downstream slope of the dam prevented a thorough inspection of the earth embankment. The trees and brush along the entire downstream earth embankment should be cut and removed. This will enable us to observe the seepage area as well as the rest of the embankment.

When you have lowered the water surface and removed the trees and brush, please inform me. If you have any questions, please call at (518) 457-1216.

Yours truly,

George Koch Supv. Dam Safety Section

New York, New York 10007

NANEN-P

6 JAN 1974

New York State Department of Environmental Conservation ATTN: Mr. George Koch 50 Wolf Road Albany, New York 12233

Dear Mr. Koch:

On 21 and 23 December 1977 members of my staff met with Village of Warwick, New York representatives regarding a Village request to investigate and evaluate an earth dam which was reportedly leaking at the base of the dam. As a result of these field inspections, it was determined that one of three earth dams forming part of a pumped storage water supply project for the Village was in fact experiencing through seepage in the vicinity of the right abutment. The dam, the lowest in both elevation and height of the three is an arched earth dam approximately 25 ft. high, 150 ft. long empounding approximately (12) million gallons of water. It has a 20-25 ft. wide uncontrolled overflow spillway at the left abutment at an elevation of approximately 5 ft. below the top of dam and a 20"d blow-off pipe extending through and at the base of the dam controlled by a sluice gate on the downstream side. Operational procedures for the three dam system call for pumping of water from this lowest reservoir to the highest from which point the water would flow by gravity to a chlorination plant and subsequently for distribution into the water supply system of the Village.

Visual observations by field inspection teams revealed through seepage in the vicinity of the right abutment from approximately half-way down the dam embankment slope of the downstream face to the base of the dam seeping at several locations. Although flow measurements could not be made due to the fact that no quantitative instrumentation NANEN-F Mr. George Koch

was available, this type of seepage posess a definite threat to the integrity of the structure which requires that immediate remedial actions be taken. In addition, a field inspection of downstream development revealed that the first of a row of one-family houses was only approximately 600 ft downstream with the Village's main population located further downstream. An evaluation of downstream impact should dam failure occur is presently being made.

In order to remove the immediate threat and insure that the seepage forces created by this through seepage do not cause dam failure the following immediate actions are recommended:

- a. Immediate drawdown of the reservoir. During drawdown observations should be made at the seeps to determine their relation to reservoir stage.
- b. The entire downstream slope should be cleared of debris and inspected in order to determine if additional seeps are present.
- c. Construct an inclined drain system with appropriate filter and collector pipes to collect and channelize seepage.
- d. Provide a pipe weir to measure and monitor discharge through the drain pipes.
- e. Construct a stabilizing berm on the downstream embankment with a minimum slope of 2½ horizontal and 1 vertical.
- f. After drawdown, the upstream face of dam should be examined and treated with bentonite in an attempt to seal the seep at its source.
- g. Install a piezometer on the downstream embankment to measure pore pressure fluctuations as a means of determining the effectiveness of the drain.

Sincerely yours,

CASPE/NANEN-F

23 January 1978

Mr. George Koch New York State Department of Environmental Conservation 50 Wolf Road Albany, New York 12233

Dear Mr. Koch:

Reference is made to letter dated 6 January 1978, concerning our inspections of the Village of Warwick's lower dam in Warwick, New York.

The results of the joint 23 December 1977 inspection with members of your staff and my Hydraulics Section regarding downstream effects revealed a potential for damage caused by a flood wave should total dam failure occur. The analysis employed approximations as to structural dimensions and stream cross sections. It was determined that the flood wave depth would be several feet above the banks at both the first critical location (3600 feet downstream of the dam) and the most downstream location (8000 feet below the dam or the middle of the Village).

Sincerely yours,

cc: Lawska (Oper. Div.) Rosen (Hydraulics Sect.) Barbero

FILE

NANEN-F Village of Warwick Dam; I.D. No. 59 21 February 1978

Mr. George Koch
New York State Department of
Environmental Conservation
50 Wolf Road
Albany, New York 12233

Dear Mr. Koch:

Reference is made to the following:

- a. Letter dated 30 December 1977 from your office to Mr. Carl Quackenbush, Supt. of Public Works, Village of Warwick regarding the downstream hazard subject dam poses, and your request to immediately lower the water surface of the reservoir.
- b. Letter dated 6 January 1978 from Col. Clark H. Benn, District Engineer, New York District advising you of the definite threat caused by the seepage mentioned in this letter and calling for remedial measures to include immediate drawdown of the impoundment.
- c. Letter dated 23 January 1978 from the undersigned describing the downstream effects should total failure of subject dam occur.
- d. Telephone conversation between Mr. John Dioguardi of my staff and yourself on 14 February 1978 in which you indicated that the Village of Warwick had initiated the cutting of brush on the downstresm slope to further observe this seepage condition but had not as of yet lowered the reservoir stage as requested in references a and b, above.

This office still considers the reported seepage in the vicinity of the right abutment to be a definite threat to the integrity of the structure requiring the immediate drawdown of the reservoir. To date no such action by the owner has been taken as indicated in reference d., above.

21 February 1978

NANEN-F Village of Warwick Dam; I.D. No. 59

It is requested that your office exercise its enforcement authority in insuring that the initial step of the recommended remedial measured outlined in reference b., be implemented immediately to obviate the possibility of dam failure with its associated downstream damage potential.

Sincerely yours,

BARBERO/NANEN-F

March 3, 1978

Mr. Carl Quackenbush Supt. of Public Works Village of Warwick Box 369 Warwick, New York 10990

Re: Warwick Dam #397 L.H.
Reservoir #1 (Lower Reservoir)

Dear Mr. Quackenbush:

This letter will confirm the remedial work that we discussed during our field inspection of the dam on March 2, 1978. The initial remedial work that we agreed upon involves lowering of the reservoir water surface and will be accomplished as follows:

- On March 3, 1978 you will begin lowering the water surface by pumping water to your upper reservoir.
- 2. On Monday, March 6, 1978 you will continue lowering the water surface of the lower reservoir by opening the sluice gate on the 20-inch diameter drain. Gravity drainage will continue until the water surface has been lowered just below the elevation of the seep. The water surface will be lowered about 8 feet.
- 3. During your dewatering operation, consideration will be given to providing enough cover over the existing water pipe in the reservoir to prevent freezing. However, the water surface will be lowered at least 6 feet.
- 4. The water surface will be kept at the lowered elevation until permanent remedial work has been completed at the downstream portion of the earth embankment.

Field inspection at the site on March 3, 1978 indicated that there was about 12 inches of snow on the frozen ice surface. About a half-inch of water was flowing over the masonry spillway. In the vicinity of the seepage area there was less snow cover than on the rest of the earth embankment and the ground surface was frozen.

Lowering the water surface is the first step in the remedial work that is required at this dam. Later, when weather conditions are favorable for construction work, additional remedial work will be necessary. This work will include placing a stone filter blanket on the downstream slope of the earth embankment.

Please keep Ken Harmer informed of your progress in dewatering the reservoir.

Very truly yours,

George Koch

Supervisor, Dam Safety Section

Mr. George Koch
N.Y.S. Dept. of
Environmental Conservation
50 Wolf Rd.
Albany, New York 12233

Dear Mr. Koch:

After our meeting and discussion on Friday, March 3, 1978, we came to the agreement we would proceed to lower the #1 Reservoir. Following are the procedures we took and the effects of these procedures.

We began the lowering by using our 40 H.P. recirculating pump and ran it through the weekend.

3/6/78- Monday A.M.- The water had lowered 10". Just after noon that same day, we discontinued the pumping and opened a 8" gate valve to proceed with the lowering.

3/7/78- Tuesday A.M.- The water had lowered 2" more. This same day I conversed with Mr. Ken Harmer of your office and explained what was being done.

3/8/78- Wed. The water had lowered 1' more, which made the level 2' below normal.

3/9/78- Thurs. - The level had lowered 8" more and the ice was all cracked loose from the shore line and lowering with the water, which we were happy to see.

3/10/78- Fri. - Water level was down 1' more.

3/13 - Monday- After the weekend the level had been lowered 5'4". The ice was still lowering with the water.

3/14- Tuesday- We had the water level down 6' and was making adjustments with the 8" valve to try and hold this level. It rained off and on during the day.

3/15- Wed. - Water level, due to the 1.41" of rain and snow melt, came up 2'6".

3/16- Thurs. - Warm weather and continued run-off raised the level 6" more.

3/17- Fri. - Level was holding.

3/20- Monday- Changed from the 8" gate and opened the 20" gate.

3/21- Tuesday- As of today, we had the level backdown 3'6".

3/22- Wed.- I called your office and asked if you had any objections to the draining completely of this reservoir and you did not.

We found due to warm weather, we could not control any level, so this is why we decided to lower it completely.

We devoted from 3/22 till 3/24 and almost had the mission accomplished, but Saturday and Sunday we got 2.9" of rain again and the rain is still continueing today, 3/27. We are in hopes that when the rain ends and we once get the water drained, we will be able to open the 20" gate fully and it will keep the level down, without any effects of some lower area downstream.

Just as a matter of information, there was no change visually in the so called leak.

Very truly yours,

Carl Quackenbush Supt. of Public Works

cc: R.A. Peluso, Wehran Engineering Jerome Caspe, Army Corps of Engineers APPENDIX C
FLOODWAVE ANALYSIS

Warnick Reservoir

"Dam Break Analysis"

Flood Wave Determination

Dec 1977 - Jan 1978

Refer to ASCE Paper No. 3915, dated May 1964, "Hydrology of Spillway Design," by A.F. Snyder For the method used in determining the flood wave.

Calculations by R.L. ALPERN C-1

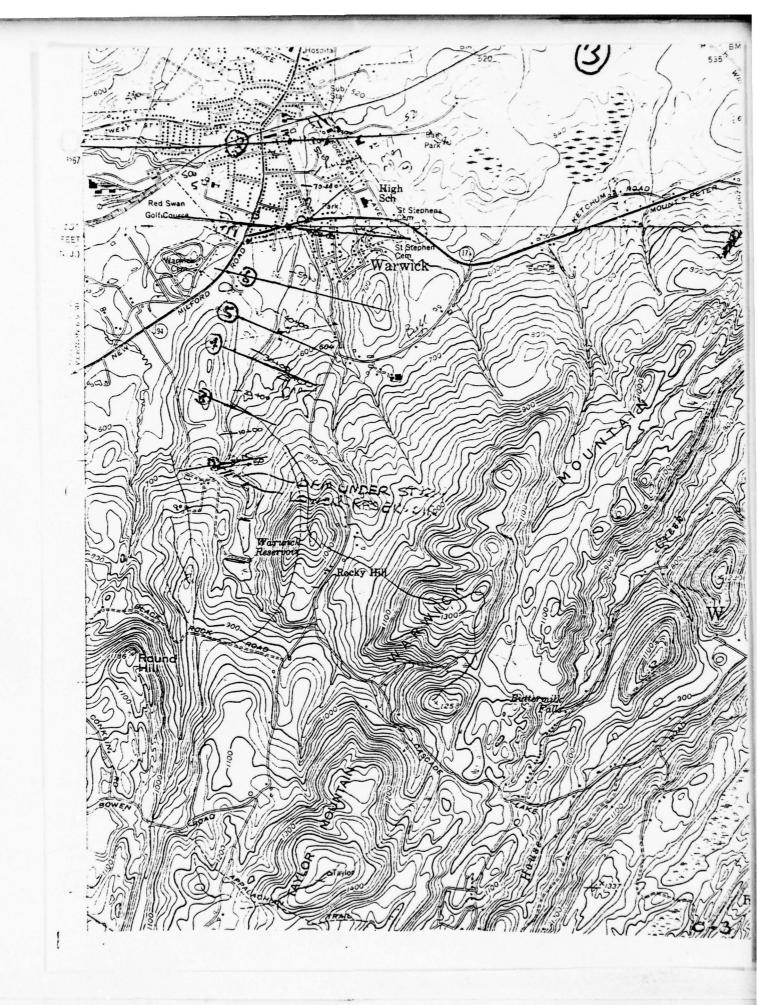

General steps required in order to perform the calculations of flood wave depths

- Volume of reservoir must be determined.
- Representative downstream sections must be chosen. Compute the value of Q at the time of breach
 - Using the steps outlined in ASCE paper No. 3915, compute the downstream flood wave depths.

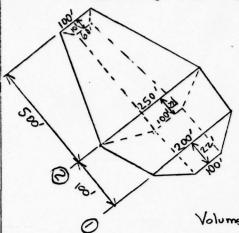

Findings

Knowing the depths at the downstream sections and the locations of the houses it was found that if the dam broke, the first set of houses at Station: 35+50 would have about 9 feet of water overflowing the banks. . From station to the town line there are no further houses in the flooded area. Once in the town limits, around station 60+00, the depth decreases to 5/2 feet above the banks but the area is more highly populated. The depth in the middle of the town, station 80+00 decreases to 2.8 feet above the banks.

To conclude, there is a potential for damage to occur by the dam breaking.

The volume of the reservoir must be found in Acre-feet

(3

Using the average end area method.

Volume =
$$\left(\frac{3300 + 3850}{2}\right)100 + \left(\frac{3850 + 300}{2}\right)500$$

= 1,520,000 ft3

The peak discharge at time of full breach using the W.E.S. equation is Qmax = $\frac{8}{27}\sqrt{9}$ K. 28 Wb Db 15

Wd = width of dam
Wb = width of breach
Yo = overall depth of dam
Db = depth of breach

For full breach K=1

 $Q_{max} = \frac{8}{27} \sqrt{32.2} (200)(22)^{1.5} = 34,699$ width of breach = 200' Say 34,700 cfs depth = 22

The steps used to calculate the flood wave depth are as follows:

Reach A - From dam to section = 2

O Compute shope index, Si, in hours

We know the depth at the dam (Upstream section) = 22'
from the dam to section 2 is 300' in length

The average depth between the two sections

must be used in the calculation: Where Dava = Dos + \$ (Dus - Dos)

DOWNSTREAM UPSTREAM

2 In order to get Dava, we must assume a downstream depth

We can try 15' as our first guess $D_{DS} = 15' \quad D_{VS} = 22' \quad D_{aVG} = 15 + \frac{1}{3}(22 - 15) = 20.7'$ we now go to figure 2, Valley storage index, ts, and for a depth of 20.7' get a value of .125

3. We are now able to compute Ts, the Index of valley storage where Ts = Lts L is in miles $Ts = \left(\frac{300}{5280}\right)(.125) = .0071$

We now have the ratio $\frac{T_5}{Si} = \frac{.0071}{.0421} = \frac{.587}{.0421}$

- We go to Fig 2., the attenuation of discharge from a breached dam. enter the bottom with $T_5/s_i = .587$ this yeilds a % of Qmax = 572% 93% Attenuated Qmax = .57(34,700) = 19432
- (3) We must check to see if the attenuated Qmax, 19432 32,277 can equal the maximum discharge at that section. $Q_{max} = \frac{8}{27} \sqrt{9} (w) (D_{os})^{1.5}$

W = width of the water surface at depth Dos $Q_{\text{max}} = \frac{8}{27} (\sqrt{32.2})(173')(15)^{1.5} = 16900 \text{ cfs} \ \angle 19 + 32 \ 32,270$

O Go to step @ and choose a greater depth C-5

to increase amax. If amax was greater than the attenuated amax, we must choose a lesser depth.

Try Dos = 16.3 Dave = 16.3 + $\frac{1}{3}(22-16.2)$ = 18.2 W = 130.205 Dave = 16.3 + $\frac{1}{3}(22-16.2)$ = 18.2 W = 130.205 Dave = 16.3 + $\frac{1}{3}(22-16.2)$ = 18.2 W = 130.205 = 170 = 100.25 .0063 $T_{5/5} = \frac{(300)}{(520)}(192) = 100.25$.0063 $T_{5/5} = \frac{(300)}{(520)}(192) = 100.25$.0063 $T_{5/5} = \frac{(300)}{(520)}(192) = 100.25$.047 = 100.25 .02910 A++. Qnax = .505 (34700) = 100.25 .02910 $Q_{7} = 100.25$.043 $Q_{7} = 100.25$.045 $Q_{7} = 100.25$.047 $Q_{7} = 100.25$.047

" $D_{05} = \frac{16.8!}{20.5} Q = \frac{19600}{322.70} Q$ section 2
