Organophosphazenes. XIV. Para Substituted Aryl and Mixed Para Substituted Aryl/Phenyl Fluorocyclotriphosphazene Derivatives.

> Christophær W. Allen\*, George E. Brunst and Michael E. Perlman

> > Department of Chemistry University of Vermont Burlington, Vermont 05405, USA

The reactions of aryl lithium reagents containing electron donating substitutents in the para position with hexafluorocyclotriphosphazene,  $P_3N_3F_6$ , have been examined. These reactions yield the appropriate monoaryl pentafluorocyclotriphosphazenes,  $P_3N_3F_5C_6H_4X$  (X = F, Cl, OCH<sub>3</sub>, CH<sub>3</sub>) in moderate yields. The monoaryl phosphazenes are converted to the geminally substituted mixed aryl/phenyl derivatives,  $2,2-P_3N_3F_4(C_6H_5)C_6H_4X$  (X = F, Cl, OCH<sub>3</sub>, CH<sub>3</sub>), by the Friedel-Crafts reaction The infrared and nmr spectroscopic data along with the mass spectrometry data are discussed in terms of perturbations of the aryl system by both the phosphazene and electron donor substituents.

## Introduction

The reactions of anyl lithium reagents with cyclic<sup>1-4</sup> and polymeric phosphazenes<sup>5</sup> have proved to be of value for the preparation of ary1phosphazenes. To date phenyl<sup>2,3</sup> tolyl<sup>2,3</sup> p-dimethylaminophenyl<sup>1</sup>, fluorophenyl<sup>4</sup> and perfluorophenyl<sup>4</sup> derivatives have been synthesized. In addition to aryl species, a wide variety of other organolithium reagents have been shown to undergo reactions with cyclophosphazenes. 6-11 This investigation involves the extension of this synthetic technique to the preparation of anyl phosphazenes with a variety of electron donating functional groups in the para position of the aryl ring. Interest in this type of compound is related to two topics of continuing interest in our studies of organophosphazenes. We have previously shown that the p-dimethylaminophenyl group functions as an effective electron donor to the strongly electron accepting fluorophosphazene moeity.<sup>12</sup> Consequently. it was of interest to prepare aryl phosphazenes with a range of electron donating groups on the aryl ring in order to probe the manifestations of these electronic effects on basic spectroscopic properties. We also have been developing organofunctional phosphazenes in order to provide starting materials for the preparation of new organophosphazenes via synthetic transformations of the exocyclic group. 10,11,13 Organofunctional arylphosphazenes would provide another possible source to new organophosphazenes.

### Experimental

<u>Materials and Measurements</u> Hexachlorocyclotriphosphazene (Ethyl Corp.) was converted to hexafluorocyclophosphazene  $(P_3N_3F_6)^{14}$  which in turn was converted to paratolylpentafluorocyclotriphosphazene<sup>2</sup> by previously reported procedures. Benzene<sup>15</sup> and diethylether were distilled over sodium. Triethylamine was distilled from potassium hydroxide. The following reagents were used without further purification: n-butyl lithium (Alfa), 1-bromo-4-chlorobenzene (Adrich), 1-bromo-4-fluorobenzene and 4-bromo-anisole (Eastman Kodak). Nmr Spectra were obtained on a JEOL C-60HL spectrophotometer as fifteen percent cyclohexane solutions. Further dilutions did not produce any change in chemical shifts.<sup>16</sup> Second order spectra simulated with the LACOON III Program. Infrared spectra were obtained on thin films or nujol mulls using a Beckman IR-20A spectrophotometer with sodium chloride disks and were calibrated with polystyrene bands. Mass spectra were obtained on a Perkin-Elmer RMU-6D spectrophotometer at 80eV. In certain cases ionizing volt ages were varied from 80 to 15 eV with the lower limit taken as approaching the appearance potential. Calibration was accomplished using perfluorokerosene. Elemental analyses were performed by the Robertson Laboratories.

<u>Preparation of Mono (p-fluorophenyl)pentafluorocyclotriphosphazene</u>. The procedure discussed here is a modification of those reported for the preparation of phenyl<sup>3</sup> and p-fluorophenyl fluorocyclotriphosphazenes.<sup>4</sup> A three-necked roundbottomed flask changed with 200 ml of diethyl ether, a stirring bar and 6.88 ml (0.06 mole) of p-FC<sub>6</sub>H<sub>4</sub>Br was fitted with a nitrogen inlet, a pressure-equalizing dropping funnel and a reflux condenser attached to a mercury bubbler. The flask was cooled to  $-78^{\circ}$  and flushed with nitrogen for 10 min. A solution of n-butyl lithium in hexame (25 ml, 0.06 mole) was admitted to the dropping funnel through a septum cup with a syringe. The butyl lithium solution was added to the p-FC<sub>6</sub>H<sub>4</sub>Br solution dropwise over a period of 30 min with constant stirring. The solution was allowed to come to room temperature and stirring was continued for 45 minutes. A second three-necked flask was charged with a solution of 15.0 g (0.06 mole) of P<sub>3</sub>N<sub>3</sub>F<sub>6</sub> in 70 ml of diethyl ether and fitted with a nitrogen inlet and a reflux condenser attached to a mercury bubbler. An angled tube with 24/40 outer joints at each end was fitted to a pressure-equalizing dropping funnel at one end while the other end replaced the reflux condenser on the flask containing the p-FC<sub>6</sub>H<sub>4</sub>Li solution, thus allowing transfer of the organometallic reagent. The dropping funnel was fitted to the flask containing the phosphazene solution. The assembled system was flushed with nitrogen at -78° and then the p-FC<sub>6</sub>H<sub>4</sub>Li solution was added at 0° over a period of 90 min. The mixture was allowed to stir for an additional 2 hours at room temperature. After the solvent was removed, 100 ml of medium boiling petroleum ether was added and the solution was stored overnight at 10°. Repeated filtrations through filter aid were required to remove all of the lithium halides. The clear solution was treated with activated carbon. After removal of the carbon and solvent, the oily residue was distilled through a vigreaux column at 0.6 mm, and the fractions boiling at 66-68° were collected; yield 6.2g (32% of theory<sup>17</sup>) of a water white liquid. <u>Anal</u>. Calcd for P<sub>3</sub>N<sub>3</sub>F<sub>5</sub>C<sub>6</sub>H<sub>4</sub>F: C, 22.17; H, 1.24; mol wt, 325. Found: C, 22.26; H, 1.32; mol wt, 325 (mass spectrum).

Using procedures identicle to those described above, para substituted monoaryl pentafluorocyclophosphazenes with the formulae  $P_3N_3F_5C_6H_4X$  (X = Cl, OCH<sub>3</sub>) were prepared. These compounds were identified by ir and nmr spectroscopy and mass spectrometry.

<u>Preparation of Geminal (p-methoxyphenyl) (phenyl) tetrafluorocyclotriphos-phazene</u>. In a typical reaction, 20 ml of benzene<sup>15</sup> was distilled into a 50 ml, three-necked, round-bottomed flask containing 1.04 ml (0.007 mole) of triethylamine and a stirring bar. The flask was charged with 6.0 g (0.023 mole) of aluminum chloride and fitted with a reflux condenser attached to a mercury bubbler and a pressure-equalizing funnel containing 1.9 g (0.005 mole) of  $P_3N_3F_5C_6H_4OCH_3$  in 5 ml of freshly distilled benzene. The flask was heated to reflux with constant stirring. After 30 minutes, the  $P_3N_3F_5C_6H_4OCH_3$  solution was added dropwise. The reaction was allowed to continue for 24 hours. After allowing the reaction mixture to cool, it was poured into a 150 ml beaker

which was one-third filled with cracked ice and contained 0.5 ml of concentrated hydrochloric acid. The layers were separated and the water layer was extracted with benzene<sup>15</sup>. The benzene layers were combined, extracted with water, aquous sodium bicarbonate and water. The benzene layer was then dried over magnesium sulfate and treated with activated carbon. The solids and solvent were successively removed and the resulting oil was heated in a sublimation apparatus at 150° and 0.5 mm. A white crystalline solid, 1.1 g (53% of theory), mp 102-103° was obtained. <u>Anal</u>. Calcd for  $P_3N_3F_4(C_6H_5)C_6H_4OCH_3$ : C, 39.49; H, 3.03; mol wt 395. Found: C, 37.53; H, 2.95; mol wt 395 (mass spectrum).

Using procedures identicle to those described above, mixed phenyl, parasubstituted aryl tetrafluorophosphazenes with the formulae  $2,2-P_3N_3F_4(C_6H_5)-C_6H_4X$  (X = CH<sub>3</sub>, F, Cl) were prepared. These compounds were identified by ir and nmr spectroscopy, and mass spectrometry.

## Results and Discussion

This investigation, when combined with previous investigations, demonstrates the broad scope of the organolithium reaction for the preparation of monoaryl-

$$P_{3}N_{3}F_{6} + Li \bigcirc -X \rightarrow P_{3}N_{3}F_{5} \oslash -X + LiF$$
  
 $X = H^{3}, CH_{3}^{2}, Cl^{18}, F^{18,4}, OCH_{3}^{18}, N(CH_{3})_{2}^{1}$ 

pentafluorocyclotriphosphazenes. Furthermore, all of these species may effectively converted to the mixed phenyl/aryl tetrafluorocyclotriphosphazenes via the Friedel-Crafts reaction.

$$P_{3}N_{3}F_{5} \bigcirc -x + c_{6}H_{6} \xrightarrow{A1C1_{3}}{(c_{2}H_{5})_{3}N} 2, 2 - P_{3}N_{3}F_{4}(c_{6}H_{5}) \bigodot -x + (c_{2}H_{5})_{3}NH^{+}F^{-}$$

$$x = H^{19}, CH_{3}^{18}, C1^{18}, F^{18}, OCH_{3}^{18}, N(CH_{3})_{2}^{1}$$

Thus, the organolithium reaction represents a good route to the synthesis of

arylphosphazenes with electron donating substituents on the aryl ring. Since aryl lithium reagents with electron withdrawing substituents are only stable at significantly reduced temperatures<sup>20</sup>, aryl phosphazenes with electron withdrawing substituents are expected to be difficult to prepare.

The infrared spectra of the aryl fluorocyclotriphosphazenes are reported in Table I. The VNPN ring vibration of the monosubstituted phosphazenes occurs between 1260-1263 cm<sup>-1</sup>. The replacement of a fluorine atom by a phenyl group leads to decrease of 8-10 cm<sup>-1</sup> in VNPN. It is of interest to observe that a variation of para substituents on the aryl ring produces small variations in the phosphazene ring vibrational frequency. A further discussion of the origin of this effect is not warrented due to broad band width (even after successive dilution) and the complex nature of the transmission of aryl. electronic effects to the phosphazene<sup>12</sup>. The magnitude of the decrease in VPNP on going to the disubstituted derivative is consistent with geminal rather than non-geminal substitution<sup>19</sup>. The geminal nature of the disubstituted derivative may also be demonstrated by the absence of a strong band which occurs in the region of 760 cm<sup>-1</sup> in non-geminal phenylfluorocyclotriphosphazenes.<sup>21</sup>

The <sup>L</sup>H nmr data for the aryl protons of the monoaryl pentafluorocyclotriphosphazenes is reported in Table II. The spectra are of the AA'BB'X type (with the exception of the para fluoro derivative which is AA'BB'MX). Although it was tempting to treat the ortho protons as a first order case, it was found that simulation of the spectra using the LACOON III program was necessary in order to obtain a consistent set of parameters. A combination of unresolved resonances and quadrupole broading due to nitrogen gave relatively broad lines so that values for the long range hydrogen-hydrogen coupling constants (J<sub>HOHO</sub>1 and J<sub>HmHm</sub>1) could not be obtained.

The chemical shifts of the protons ortho to the phosphazene ring are essentially constant for the para substituent being CH3, Cl or OCH3. Since the geometry of the system stays constant through the series, the ortho shifts are controlled by a combination of the anisotropic and electronic effects of the phosphazene ring. The ortho shift for the para fluoro derivative is significantly removed from the others in the series suggesting a stronger involvement of the para substituent in perturbation of the aryl ring electronic structure in this case. In para disubstituted benzene derivatives, one generally observes that the combination of a strong electron donor and strong electron acceptor produces a large difference in the ortho and meta chemical shifts ( $\Delta$ om) while is cases where the descrimination between the groups is less dramatic, the value of Aom is smaller. In the molecules under consideration in this investigation, the strongly electron withdrawing effect of the pentafluorocyclotriphosphazene moiety 12, 16, 22 combined with good  $\pi$  donors (e.g. F, OCH<sub>3</sub>) results in significantly larger values of  $\Delta om$  than when the phosphazene is combined with weak electron donors (e.g. CH2, Cl). The phosphorusortho hydrogen coupling constant  $(J_{PHO})$  is of the same order of magnitude as previously reported for aryl phosphorus (v) compounds.<sup>16,23</sup> The better  $\pi$ donors (F, OCH<sub>2</sub>) exhibit lower coupling constants while the poorer electron donors (C1, CH3) exhibit higher values of JPHo. The more electron density in the aryl ring, the lower the effective charge on the ortho hydrogen atom and hence one observes a reduction in the value of J<sub>PHO</sub>. In keeping with previous observations<sup>24</sup>, the small variation is the hydrogen-hydrogen coupling constant, J<sub>HoHm</sub>, is related the substituent group electronegativity values.

The mass spectra for the monoaryl pentafluorocyclotriphosphazenes are reported on Table III. The basic fragmentation process observed is the same as previously established for the monophenyl derivative.<sup>25</sup> This consistency throughout a series of compounds is important in the application of mass spectrometry to the identification of new compounds. Features which are unique to individual molecules can usually be related to the known fragmentation tendencies of the organic molety e.g. loss of the methyl group in the para methoxy derivative and tropyllium ion formation in the para tolyl derivative.

The mass spectra of the mixed aryl/phenyl tetrafluorocyclotriphosphazenes (Table IV) are also understandable in terms of the basic process established for phenyl fluorocyclotriphosphazenes<sup>25</sup> with perturbations reflecting para substituent fragmentation. Organic group substituent decomposition makes significant contributions to the mass spectra of the diorgano derivatives. particularily in the para methoxyl and tolyl derivatives. The basic phosphazene fragmentation route observed is the successive cleavage of the aryl groups which is characteristic of geminally substituted derivatives.<sup>25</sup> Thus, the mass spectrometry data confirm the infrared results in the assignment of the geminal configuration to the disubstituted derivatives (the expected product in a Friedel-Crafts reaction<sup>19</sup>). It is of particular interest to compare the intensity of the ion resulting from the loss of the phenyl group  $(P_3N_3F_4C_5H_4X^{\dagger})$ compared to the ion resulting from the loss of the para substituted aryl group  $(P_3N_3F_4C_6H_5^+)$ . Previously, we have shown that a phenyl group is lost in preference to a para dimethylaminophenyl group in geminal phenyl/paradimethylaminophenyl fluorocyclotriphazenes and this observation was attributed to higher bond strength in the phosphorus-paradimethylaminophenyl unit than in the phosphorus-phenyl bond.<sup>25</sup> The tendency to lose a phenyl group in preference to the aryl group with an electron donating substitutent is observed in most of the mixed aryl/phenyl derivatives in this investigation. The apparent reversal of this trend in the para chloro derivative relates to the fact that there are two possible precursors to the  $P_3N_3F_4C_6H_5^+$  ion i.e.  $P_3N_3F_4(C_6H_5)C_6H_4C1^+$  and  $P_3N_3(C_6H_5)C_6H_4^+$ . The mass spectrum of  $P_3N_3F_4(C_6H_5) C_6H_4CH_3$  is rather complex with no  $P_3N_3F_4C_6H_5^+$  ion and a very intense ion

associated with tropyllium derivative. In order to insure that the observed intensity differences are related to thermodynamic parameters, the spectra of the two derivatives with strong electron donors (fluoro and methoxy) were run at successively lower ionization energies until the region approaching the appearance potential was reached (approximately 15 to 18eV). In the para methoxyl derivative the intensity difference between the  $P_3N_3F_4C_6H_5O^+$ and the  $P_3N_3F_4C_6H_5^+$  ions increases at lower ionization energies. While in the case of the para fluoro derivative, the ratio of the  $P_3N_3F_4C_6H_4F^+$  to the  $P_3N_3F_5C_6H_5^+$  ion intensities approaches unity at lower ionization energies. Thus in the paramethoxy case, phosphorus-carbon bond enthalpy is greater in the bond to the para substituted aryl group. In the para fluoro derivative, there is no preferential phosphorus-carbon stabilization in the appearance potential region consequently the intensity difference at higher ionization energies is related to kinetic effects. Two of most probable kinetic effects which are reasonable for this system are stabilization of the developing positive ion by the electron donating para-fluorophenyl moiety and the superior leaving group ability of the phenyl group.
