20. ABSTRACT *(Continue on reverse side if necessary and identify by block number)*

At the Naval Research Laboratory highly portable intelligent terminals are being utilized aboard oceanographic platforms for the acquisition and storage of total magnetic field measurements. Described in the paper is the design and implementation of the data acquisition system which includes a detailed description of the hardware and software utilized.

CONTENTS

A HIGHLY PORTABLE DATA ACQUISITION SYSTEM FOR TOTAL MAGNETICS FIELD MEASUREMENTS

I. INTRODUCTION

The Acoustic Media Characterization Branch of the Acoustics Division of NRL has since 1971 conducted magnetic field studies for the Navy in many areas of the world. Much of this work has been accomplished using aircraft to conduct the magnetic studies. The resultant data has been compiled into magnetic anomaly charts of the oceans of the world. The information is utilized by DOD for interpretation of the tectonic history of the area. These interpretations utilize state of the art theories of sea floor spreading and plate tectonics.

Many of these magnetic studies are performed on aircraft and ships of opportunity or "piggybacking" other experiments. During some of these data gathering experiments it is inappropriate or impractical to place a mini-computer system aboard the aircraft due to size, weight or the resources required to install, maintain and operate a computer system.

NRL has developed a highly portable, compact, lightweight and easy to operate data acquisition system for acquiring magnetics field data and navigational position information. The portable magnetics data acquisition system has been used successfully yielding results comparable to the mini-computer system.

II. PORTABLE DATA ACQUISITION SYSTEM

The portable data acquisition system is based around a Hewlett-Packard HP264X intelligent terminal. Figure 1 is a photograph of the terminal. The feature of the terminal that makes it intelligent is the programmable microprocessor internal to the terminal. Also, all of the necessary components of a computer such as internal storage, external storage and interface capability to peripherals provide the capability of making the terminal a data acquisition system.

The HP264X was selected as the data acquisition system because it had all of the salient features required such as, programmable processor, internal memory, external cassette storage, parallel and serial interfacing capability, portability and software development tools. In addition, several of these units are available at NRL and being used as computer terminals. In fact, the HP264X can be considered a well packag-

Manuscript submitted June 11, 1980.

ed, self-contained microcomputer.

A functional diagram of the portable terminal magnetics field data acquisition system is shown in Figure 2. The system consists of a Geometrics Model G801/803A magnetometer, a CHRONO-LOG Series 70000 Time Code Generator and a NRL designed Litton Interface that obtains aircraft position information from the aircraft Litton Model 72 Inertial Navigator. The components of the system are described below.

1. Terminal Electronic Circuit Boards

An interior view of the terminal is shown in Figure 3. There are fifteen circuit boards that can be inserted directly into the terminal. Ten of these boards are required for control of the terminal, with the microprocessor residing on one of these boards. To use the HP264X as a data acquisition device two high density HP13297A-003 32K Byte RAM (Random Access Memory) Boards are required. The strapping configuration of these boards are given in Table 1. This memory is used for display, programs, temporary data storage and assembling and debugging programs. The HP264X in this configuration leaves five empty slots for interfacing to external sensors.

2. I/O Terminal Interfaces

The HP13255 Terminal Duplex Register Board described in Reference 1 was selected for interfacing with the magnetometer, digital clock and Litton Inertial Navigator Interface. All of these devices provide Binary Coded Decimal (BCD) outputs at TTL logic levels. The Duplex Register Board contains 8 data receiving lines and 8 status lines. It was recognized that the 8 status lines could be used for data input as well as the 8 data lines resulting in 16 data lines for input. The polarity of the status lines on the interface is reversed from the data lines except for bits zero and one. By using the status lines the input capacity was increased from five 8 bit words to five 16 bit words, thereby doubling the data acquisition capacity of the terminal. Also, by using the status lines the 16 bit four character BCD output of the magnetometer and Litton Navigator Interface was fully compatible. The problem of polarity was handled with software by masking the two status bits of opposite polarity complementing the remainder and adding the two bits to the remainder to reform the byte.

3. External Storage

The HP264X Terminal has two cassette drive units mounted below the display. Each cassette is capable of storing 110K Bytes of information. The information stored on these cassettes are source, object, assembler and debugger programs and the data acquired from the magnetics

data acquisition system. The cassettes can be operated using functional keys from the keyboard or under program control. Both ASCII and binary tapes can be read and written by the terminal.

4. Litton Interface

The interface between the Litton Inertial Navigator and the data acquisition system was specially designed and built at NRL. The Litton Navigator sequentially outputs inertial navigation information on a continuous basis. The function of the interface is to service a request for data from the data acquisition system. Upon request from the controller the interface obtains and stores latitude, longitude and heading information. After acquiring this information the interface interrupts the terminal data acquisition system. Upon receiving the interrupt the terminal goes through a "handshake" sequence with the interface three times to acquire the latitude, longitude and heading which is sequentially multiplexed to the output lines of the interface.

The interface is connected to the terminal using two duplex boards. Two boards are required since eight BCD characters form a position word. The terminal I/O board addresses of the four most significant characters and the four least significant characters are given in Table 2. The addresses are accomplished by configuring jumpers at appropriate locations on the duplex board.

5. Magnetometer

The magnetometer measures the magnetic field intensity at either preset or continuous intervals. Five BCD TTL compatible digital characters are output through a connector on the back of the unit to the terminal and also output to the display of the magnetometer. Since each terminal interface is capable of accepting four BCD characters two interfaces are required. The most significant character from the magnetometer is interfaced to one eight bit duplex board while the four remaining characters are interfaced to a second duplex board in the terminal. The I/O strapping configurations are given in Table 2. The strapping consists of assigning the board an address that can be read by the program. The addresses of each respective board is given in Table 2.

6. Digital Clock

The function of the clock is to provide digital time in order to be able to correlate and interpolate data when future processing is performed. The clock provides in BCD format at TTL signal levels day of year, hours, minutes and seconds. In order to conserve input capacity, minutes and seconds consisting of four BCD characters were interfaced to the terminal using one duplex board. Day and hour are hand recorded on the cassette cartridge and time information is reconstructed when

further processing is performed. The address of the terminal interface board is given in Table 2. Also, it should be noted that there are several manufacturers of digital clocks which can be used and have been used since they function similarly to the CHRONO-LOG.

III. SOFTWARE DESCRIPTION

Programs for the intelligent terminal can be developed by preparing the source program and using the assembler available on the terminal or by using an HP1000 mini-computer system to prepare the program and provide a cross assembly for loading into the terminal. Since the debugging of the program can only be performed on the terminal the program for the terminal magnetics system was developed on the terminal.

The terminal uses a Intel 8080 compatible microprocessor. The microprocessor differences are in the way I/O is managed. Therefore, the program with the exception of I/O is Intel 8080 compatible. The terminal has many software subroutines stored in Read Only Memory (ROM) that can be used by the program by addressing the starting location of the subroutines. These subroutines, since they are stored in ROMs can not be altered. The routine PUTIO for performing I/O to the terminal display and cartridge tape units was used. This routine will write ASCII records to the display and either tape drive depending upon the device specified. The terminal magnetics program has been programmed to use only the right tape drive to store data.

The terminal has a 10 millisecond internal clock. The clock is used to schedule the magnetics program by storing the number of 10 millisecond intervals required in a location called TIMER which the terminal executive system decrements. Upon decrementing the location to zero the executive system software transfers control to a predetermined location. The starting address of the user program is stored at this location which in turn permits the scheduling of subroutines. The magnetics data acquisition program was scheduled to execute every three seconds. This required the storing of 100 in the location TIMER which equates to one second and executing the timer program three times. This was required since the microprocessor is organized around an 8 bit word which has 127 as its largest positive number.

The terminal data acquisition program is entered by transferring control from the terminal executive program to the program CHTIMO. The function of CHTIMO is to schedule the data acquisition program to run at three second intervals. This is accomplished by checking for the TIMER location to go to zero and the number of repetitive seconds to go negative. When the repetitive seconds have expired software control transfers to the main program CONTRL, otherwise a return to the terminal executive program is executed.

The program CONTRL is used to call four major subroutines, namely, INIT2, INPUT, PROCES and OUTPUT. These four programs are discussed below.

1. Subroutine INIT2

The program INIT2 stores 100 in the location TIMER which allows the terminal executive system to decrement the location TIMER 100 times, which takes one second before going to zero. Also, the program sets the repeat factor of this program at two in order to obtain three second intervals between the magnetics program execution. The program INIT2 is called every time the program CHTIMO calls the program CNTRL.

2. Subroutine INPUT

The function of subroutine INPUT is to obtain the data from the external sensors and devices. It accomplishes this task by requesting data from the devices using a memory mapped I/O scheme. All of the five interface boards in the terminal have a unique address determined by the strapping configuration on the board which are given in Table 2. Under program control a request is made of the sensor, or sensor interface to send data. The data is buffered into the terminal interface I/O board. By addressing the terminal interface board with its unique address the data can be handled by the microprocessor under program control.

In the case of the Litton navigation information the process is repeated three times since the data is multiplexed out using the same two interface boards in order to obtain latitude, longitude and heading of the aircraft.

3. Subroutine PROCES

The program PROCES is used to manipulate the data into a format suitable for display and storage on cassette tapes. The first step in the process of preparing the data for output is to convert the BCD characters to an ASCII format. The status byte consisting of bits zero and one being of opposite polarity to the remaining word must be complemented and the word reformed. Following all the status words and data words being in the same BCD format, the data is manipulated by an algorithm that replaces the BCD character with its equivalent ASCII character.

In the case of latitude and longitude the first bit of the status byte is masked and tested for 0 or 1, which determines North or South for latitude and East and West for longitude.

4. Subroutine OUTPUT

In order to output the data to the display for monitoring and

the cartridge tape for storage a terminal executive system routine called PUTIO is utilized. The program moves the data in ASCII format to a terminal system output buffer and PUTIO is called. PUTIO places the data on the display and the right cartridge tape.

IV. PROGRAM DEVELOPMENT

The source program is written in a compatible INTEL 8080 language with the only exception being the I/O operations. These I/O operations are accomplished using programs stored in a terminal ROM.

1. Preparing the Program

For assembling and loading, the source and binary programs must reside on cartridge tape. The source program can be placed on the tape by entering the source code into the terminal display memory through the terminal keyboard. Once in the display memory the source code is transferred to tape using the terminal function keys which provide the capability to transfer data between the terminal and other devices. An alternate method of obtaining the source code on tape is by keying the program into a file using the HP1000 mini-computer system. The file can then be edited and "dumped" to cartridge tape in ASCII format.

2. Assembling the Program

The HP13290B Debugger/Assembler is a commercially available product from Hewlett-Packard, and it resides on cartridge tape. By placing the tape in the left drive of the terminal it is loaded using the function keys on the terminal. Once having loaded the assembler the source program which resides on tape is placed on the left drive and a blank tape to receive the assembled code in the right drive. After having successfully completed the assembly the right tape with the assembled code is then placed in the left tape drive and under keyboard command is loaded into the terminal. At this point the program is ready for execution. Operating instructions for the magnetics data acquisition system are given in Appendix II. An alternate manner of assembling the program is to use the cross-compiler available on the HP1000 mini-computer system. The assembled program is stored on tape in the same format as the assembly on the terminal. Refer to Reference 2 for specific instruction on using the HP13290B Debugger/Assembler.

V. RESULTS

The major benefits of the Magnetic Field Terminal Data Acquisition System is its compactness (all data acquisition components are integrated into the terminal), weight of 45 pounds and reliability. This can be compared with the mini-computer system which resides in a 56 inch equip-

ment rack which weighs approximately 600 pounds.

Experiments collecting magnetic field data have shown the accuracy of the terminal data acquisition system is identical to the accuracy of the mini-computer system. However, when the mini-computer system is utilized, the magnetics data can be processed to completion, whereas, the data stored by the terminal data acquisition system must be further processed by the mini-computer at some future time. Additionally, the storage capacity of the mini-computer system is far greater than the terminal resulting in the mini-computer being operated for much longer periods of time before the data must be stored in another manner such as nine track 800bpi magnetic tape.

The terminal Magnetics Field Data Acquisition System has been proven to be a viable alternative to the mini-computer when the mini-computer system is inappropriate. The terminal systems have been utilized to acquire and process data for Airborne Expendable Bathythermograph (AXBT) experiments and recording the environment during acoustic studies as well as magnetic field experiments.

APPENDIX II

OPERATING INSTRUCTIONS FOR THE TERMINAL MAGNETICS FIELD DATA ACQUISITION SYSTEM

1. Turn on power to the terminal, Litton Interface and Clock.

2. Set the thumbwheel switch on the Litton Interface to "0".

   Explanation: By setting the select code on "0" Latitude will be selected and displayed on the interface. The terminal receives latitude information from the display.

3. Insert cartridge tape marked Debugger/Assembler in left tape drive of terminal.

4. Press the key marked READ on the terminal. Wait for completion.

   Explanation: The first record of the Debugger/Assembler tape will be displayed.

5. Press the key marked f2 on the terminal. Wait for completion.

   Explanation: By pressing f2 the second record on the Debugger/ Assembler tape will be loaded into the terminal memory. The message "OK>" will be displayed on the terminal.

6. Remove the Debugger/Assembler tape from left drive and insert the tape marked Magnetics Version 13 Binary.

   Explanation: This is the binary magnetics program to be loaded into terminal memory.

7. Type the characters "L" and "CR" (Carriage Return). Wait for completion.

   Explanation: This sequence will load the binary program into terminal memory. The message "HP264X ASSEMBLER V2.0" will appear on the terminal display followed by an "OK>" prompt.

8. Place a blank cartridge in the right terminal drive.

   Explanation: The data will be recorded on this tape cartridge. The cartridge should be unprotected by moving the protect lever to the left position. The tape cartridge should be labeled by hand. The recommended labeling is day of year and starting hour of tape.

9. Type "/9169" then "CR" on the terminal.

   Explanation: An instruction in location $9169_{(16)}$ must be modified so that control will be transferred from the terminal executive software to the magnetics program. An "87" will appear on the display.

10. Type "601A" then "CR" on the terminal.

    Explanation: The starting location of the magnetics program is $601A_{(16)}$. An "0" will appear on the display.

11. Type ":" (colon) on the terminal.

    Explanation: The ":" will terminate the modification process. An "OK>" will appear on the terminal display.

12. Press the RESET button on the terminal only once.

    Explanation: Pressing the RESET button once forces a transfer in the terminal executive to the magnetics program. The program will start execution.
