INTRODUCTION

PURPOSE.

Efforts to collect Air Traffic Control Radar Beacon System (ATCRBS) transponder performance data from military aircraft at Dobbins Air Force Base (AFB), Georgia, were made by Federal Aviation Administration (FAA) Technical Center personnel at the request of the FAA/ Southern Region. Difficulties were encountered during the collection process which emphasized the need for further investigation. The purpose of this report is to present information obtained to date for use in field problem investigations and consideration.

BACKGROUND.

The Atlanta Terminal had reported difficulties in tracking low flying military aircraft, particularly high performance aircraft such as the F-105, operating out of Dobbins AFB. This same type aircraft has also been reported as having transponder difficulties by the New York and Washington Centers and by other traffic control facilities. The problems reported are: poor tracking, loss of target, and/or excessive coasting.

DISCUSSION

The transponder performance analyzer (TPA) data collection at Dobbins AFB resulted in failure for several reasons (none of which necessarily imply malfunctioning or inoperative transponders). First, reply pulse amplitude variations of 2:1 were observed. Second, certain interrogation sequences automatically generated by the TPA resulted in erroneous interrogations for the transponders, e.g., modes I and II. The replies were then erroneously interpreted by the TPA resulting in false data. Third, lack of knowledge concerning the military transponders and, in particular, specific aircraft installations resulted in data inconsistencies and misinterpretation.

It was discovered during investigation of the various problems that a number of high performance fighter-type aircraft utilize dual antenna systems. The F-105, for example, has one antenna on top, forward of the cockpit, and a second antenna on the bottom, aft, behind the hook (see figure 1). The antennas are switched alternately at a 38 hertz (Hz) rate. (A switch inside the cockpit selects either the top only, bottom only, or both which automatically switches from one to the other at the 38 Hz nonsynchronous rate.) Table 1 lists other aircraft with known switch capabilities, rates, etc.

A high percentage of these aircraft also utilize skin or flush mounted antennas as shown in figure 2 for the F-106 aircraft. The skin-mount or "pie plate" antennas are not considered as efficient as stub antennas; however, aerodynamic considerations require the flush mounted design with sacrifice of antenna performance.

A third factor in the antenna system is the long cable runs required in aircraft such as the F-105. The F-105 has approximately 40 feet of cable run to the tail antenna and results in additional signal attenuation which could become critical in fringe areas of Maintenance personnel have coverage. also indicated radiofrequency (RF) losses through the antenna switch as high as 10 decibel (dB), which indicates a problem in the switch. This would seriously affect both power and sensitivity of the transponder.

One of the most important factors of consideration is the antenna pattern of the aircraft. This is particularly true where installations result in nonsymmetrical patterns. This is also one of the most difficult measurements to conduct and is usually done by modeling.

confirmed, that certain type aircraft Surveillance Testing (TFAST) with utilize the antenna on a time share an ARTS III input/output processor (IOP) basis. used for tactical air navigational aid The TFAST uses a 4-foot open array (TACAN), ATCRBS, and digital communications on a time share basis. In addition, certain aircraft installations are reported to use cross suppression from distance measuring equipment (DME) interrogation to ATCRBS transponder to prevent front end overdrive of the transponder. This time share and cross suppression would reduce still further the possible hit count from that aircraft.

At some installations, preventive maintenance is also a problem area with the military transponders. The transponders are only removed and repaired if found defective on ground checks, i.e., periodic maintenance and calibration are not performed.

The F-16 aircraft uses a dual diversity antenna system with dual antennas; the transponder replies on the same antenna that receives the strongest interrogation This system should provide signal. reasonably satisfactory operation provided there are no excessive losses (3 dB or less) in the cabling and connections.

FLIGHT CHECKS.

After consideration of the above information, it was decided to conduct flight tests with both F-105 and F-106 aircraft. With the cooperation of the New Jersey Air National Guard, an F-105 was scheduled from the 108th Tactical Fighter Wing McGuire AFB, and an F-106 from the 177th Tactical Fighter Wing, FAA Technical Center, Atlantic City Airport, N.J. Both aircraft flew direct from Atlantic City (ACY) omnidirectional radio range (VOR) to Waterloo, Maryland (see figure 8), and returned. This is a distance of approximately 50 miles one way. Both aircraft were visual flight rules (VFR) at an 4,500 feet and flew at altitude of different times to minimize garbled tables 8 and 9 present the data for the beacon replies.

It also has been reported, but not The Terminal Facility for Automation and The same antenna is reportedly was used for data collection purposes. antenna with a gain of 23 dB and operating at 12.74 revolutions per minute The antenna was developed by (rpm). Hazeltine Incorporated, and is the developmental predecessor to the 5-foot array presently in process of deployment to field facilities. The site utilizes an Air Traffic Control Beacon Interragator (ATCBI)~5 System and site parameters were adjusted for 160 watt (W) transmitter output with approximately 90 W into the antenna, PRF of 343, 1:1 interlace, Side Lobe Suppression (SLS) ON, and Sensitivity Time Control (STC) curve adjusted for 39 dB.

> The ARTS hit count parameter for target declaration (HY4) is adjusted for 4. No coverage problems have been found with The normal ARTS EXTRACTOR the system. program was used for data collection to record target replies, target reports, range, azimuth, altitudes, beacon code, etc.

> The F-105 made three round trips at the 4,500 foot altitude to approximate the situation at Atlanta. The first run was using the top antenna only, the second run the bottom antenna only, and the third run both antennas. The pilot was instructed to fly both modes 3A and C; however, mode C was not turned on until the third run with both antennas.

> The F-106 aircraft only flew one round trip since the pilot does not have control of the antenna switching. This aircraft flew the same flight scenario as the F-105, i.e., 4,500 feet VFR, modes 3A and C.

FLIGHT DATA ANALYSIS.

Computer printouts are provided for each run of the test aircraft. Tables 2 thru 7 give the data for the F-105 runs;

F-106 readings in table 2, the number of displayed variations in to about 12 replies were approximately 11 to 12 as miles. The remainder of the inbound leg the F-105 was inbound to begin his first remained good. run. The hit count decreased to approximately 5 in the cone of silence fringe The F-106 flight showed some minor area, then increased to a maximum of 8 to 9, then decreased to about 4 as the miles, where the count decreased. aircraft started to turn at Waterloo (see table 2). The inbound leg increased to about 12 replies as the top antenna was reasonably unobstructed or unshielded on the inbound leg. It is noted that the run length was twice the hit count minus one. i.e., 2 x HC-1 (for hit count of 12, the run length was 23). This coincides with the site 1:1 interlace pattern since the pilot did not have mode C (altitude) turned on.

The data from the second run (bottom antenna only) indicates a hit count of 11 to 12 at the start, with a gradual decrease to 8 to 9 at Waterloo when he began his turn. The aircraft was not detected with even a single hit on the The next reply, after the inbound leg. turn at Waterloo, came after the aircraft had passed over the site and was outbound again. Run length of the outbound was, again, approximately twice the hit count.

The third run was with mode C on and the antennas automatically switched (alternating) between the top and bottom at the 38 Hz rate. The aircraft flew about 10 miles offset from the radial on the inbound leg at the request of local air traffic control. This resulted in partial visibility of the bottom antenna and some replies from the bottom antenna were recorded. As indicated by the data, both the hit count and run length were good and solid from about 9 miles out to approximately 21 miles. At this point, both hit count and run length began decreasing to 8 to 9 hits at 28 miles. This remains reasonably constant for the remainder of the outbound leg. The inbound hit count and run length were reasonably constant at 8 to 9 in to about 32 miles, at which point the hit count jumped significantly. At about 25 miles

As observed from the hit count the count dropped significantly and

fluctuations in hit count out to about 40 The inbound leg showed immediate improvement when the aircraft began the inbound leg. With few exceptions, this showed good solid hit count and run length.

IMPACT ON ARTS.

It is evident from the data presented that high performance military aircraft, particularly F-105's, present problems in the ATCRBS fringe areas of coverage. The operational ARTS systems very frequently have high hit count requirements for target declaration to reduce/eliminate false targets and ring-around. Hit count requirements of 11 for 3A/C and 7 for 3A only are not unusual in the field systems. In these systems the F-105 would have been lost for significant portions of the flight. For example, it would have been lost from about 32 miles out on the outbound leg of the first run. The inbound leg would probably have been tracked, but would have been marginal or intermittent. The outbound leg with the bottom antenna would probably have been tracked to the turn at Waterloo. Again, the inbound leg was never detected or tracked. With the antennas alternating at 38 Hz, the F-105 would not have been tracked in an operational ARTS with an 11-hit count requirement beyond approximately 28 miles on the outbound, and would have been picked up again at about 32 miles on the inbound leg. The target would have been intermittent from that point in to about 12 miles, where it would have been solid.

The F-106 would have been tracked on the operational ARTS system with firm code and altitude validation with only one or two holes on the outbound leg out to about 40 miles. The target would have been lost at this point. The inbound leg was solid all the way, except one hole would have been lost.

It is again noted that the tracking data 2. are for 4,500 foot altitudes. These data the type used in the F-16 aircraft would be significantly different at would alleviate the coverage problem; higher altitudes and would show different however, older obsolete aircraft would pattern and shielding effects.

The coverage problems appear to be with 3. the older type aircraft and have existed parameter HY4, in those facilities with since introduction of the specific high values, would improve tracking of aircraft into the military fleet. introduction of sophisticated air traffic control equipment, such as ARTS and NAS, has significantly magnified the effects of the problems with the more stringent input data requirements. In short, holes or gaps in the run length were not so It is recommended that: noticeable in the older broad band systems because the display phosphors and 1. the human eye tended to integrate the (ARTS) and National Airspace System target blip. The new digital systems are (NAS) facilities that experience sensitive to even 1 hit/miss in marginal conditions (e.g., a difference from 10 to aircraft reduce the hit count or sliding ll hits means the difference in target window requirement for target declaration declaration at some facilities). It is to 7 hits. This would enable target also believed that holes of 10 misses (sliding window width in the NAS) could result in target splits in the NAS.

The new dual diversity antenna system approach/departure patterns at military used in the F-16 would alleviate the air bases be investigated to provide more coverage problem in older aircraft; broad side visibility to the Air Traffic however, it is highly improbable that Control Radar Beacon System (ATCRBS). these aircraft would be retrofitted from the economic factor alone. A large percentage of the aircraft are obsolete iarized with the military ATCRBS and assigned to Air National Guard or characteristics with the view point of reserve activities.

CONCLUSIONS

It is concluded that:

The F-105 and similar type military aircraft present serious tracking problems in the Automated Radar Terminal (DOD) to determine what improvements, if

for four antenna scans where the target System (ARTS), particularly in the low altitude fringe areas of coverage.

> A dual diversity antenna system of not be retrofitted due to economics.

Reduction of the ARTS hit count The the high performance aircraft.

RECOMMENDATIONS

Automated radar terminal system difficulties in coverage of military declaration during one switch time (half cycle) of the aircraft antenna.

2. The possibility of modifying

3. Air traffic controllers be familpossibly changing procedures in problem areas and/or requesting the pilot to select top or bottom antenna (on aircraft with that capability) to provide better coverage.

4. Additional investigation and analysis be jointly conducted by the Federal Aviation Administration (FAA) and the United States Department of Defense any, can be made.
