ABSTRACT

Studies were initiated to inventory and classify the training structures along the Iowa bank of the Upper Mississippi River Pools 9 through 19. A total of 595 wing and closing dams were inventoried. Physical data collected from each dam site included water depth and river bottom contour, current velocities, and substrate samples. Data indicated that 217 (36 percent) of the dams within the study area had been completely eroded, covered with bottom sediments, or were physically removed by the Corps of Engineers. The remaining dams were sorted into twelve definable groups based on their physical characteristics, hydraulic regime and effect of the structure on the surrounding area.

STUDY OBJECTIVE

Classify and aggregate wing dams and closing structures on the basis of physical characteristics, hydraulic regimen and effect of the structure on the surrounding area.

INTRODUCTION

The Upper Mississippi River as originally defined by the Upper Mississippi River Conservation Committee (UMRCC) flows 926 miles from Hastings, Minnesota southward to Cauthersville, Missouri (Rasmussen, 1979). This section of the Great River consists of over 432,000 surface acres and provides a variety of commercial and recreational uses. Approximately one-third of the river (312 miles) flows along Iowa's eastern border and consists of over 191,000 surface acres (Rasmussen, 1979). An estimated 46,000 Iowa sport fishermen expend 1.2 million man-days harvesting nearly 33 fish per acre (Anonymous, 1976). Commercial fishermen on the upper river number about 2,000 each year and harvest approximately 11 million pounds of fish annually, valued at 1.2 million dollars (Anonymous, 1978).

Historically, since 1820, the Mississippi River has been "improved" for one purpose: "to keep the river open for a highway of commerce" (Rasmussen, 1979). During the mid 1800's, this work consisted mainly of clearing and snagging debris from the channel. In 1878, Congress authorized a four and one-half foot channel and the U.S. Army Corps of Engineers (COE) began to systematically construct rock and brush wing dams, closing dams, and bankline revetments (Tweet, 1975). Due to the success of experimental wing dams at Pig Eye Island (River Mile 834) and other locations, several thousand feet of wing and closing dams were built on the Upper Mississippi River by 1879 (Tweet, 1975). The wing dam proved to be an easy and permanent solution for maintaining the navigation channel. Congress authorized the Corps of Engineers in 1907 to build a six foot channel. This was accomplished by building more wing dams, dredging, and constructing additional locks. The Rock Island District alone estimated that the six foot channel would need an additional 2,000 wing dams, each 100 to 300 feet long (Tweet, 1975). By 1930, when the six foot channel was 82 percent completed, Congress authorized a nine foot channel. The wing and closing dams were not adequate to maintain the new nine foot depth. Consequently, the U.S. Army COE constructed the existing

series of 29 concrete locks and dams. Since the completion of the locks and dams in 1933, many of the training structures have been removed or repaired (Appendix I). The present navigation channel is maintained by manipulating water flows through the locks and dams and by hydraulic dredging the problem areas.

STUDY BACKGROUND

The earliest wing dams on the Mississippi River were probably built by lumbermen and raftsmen during the mid 1800's (Tweet, 1975). They were crude brush dams held in place by wooden stakes and were used to wash out sand bars, thereby deepening the navigation channel. However, they seldom lasted more than a few years before deteriorating.

Major Warren (COE) was directed in 1866 to determine the most feasible means of maintaining a four and one-half foot channel (Tweet, 1975). Most rivermen believed that closing side chutes and narrowing the natural channel was the best means of improving navigation. Major Warren requested that two experimental dams be built. A closing dam was built at Prescott Island (River Mile 811) and a wing dam was built near the foot of Lake Pepin (River Mile 763.5). Both dams proved successful.

C.W. Durham (COE) built experimental wing dams at Pig Eye Island and eight other locations in 1873 (Tweet, 1975). The dams were constructed by driving two tiers of poles along the wing dam length nine feet apart. The space was then filled with willow brush weighted down with sacks of sand. These dams were very successful.

A total of 336.4 miles of wing and closing dams had been constructed by 1907 by engineers and contractors on the Upper Mississippi River (Tweet, 1975). Willow mats weighted down by rocks were used in the construction of most wing and closing dams until 1911 (Figure 1). By then the willow supply ran out and lumber mats were substituted. Approximately 73 miles of wing and closing dams were constructed within the study area prior to 1932 (Appendix I).

The construction of the locks and dams in the 1980's significantly altered the Upper Mississippi riverine environment. The locks and dams created a series of river lakes from the existing free flowing river. At first the impoundment of the river expanded water surface area and vastly increased aquatic productivity

Figure 1. Cross section of a rock and brush wing dam on the Upper Mississippi River.

(Tweet, 1975). The increased water depth did provide a much improved navigational system. However, it was soon apparent that the series of locks and dams created a river that was less dynamic than the unregulated system. The construction of the locks and dams started an accelerated, man-induced aging process. The backwater areas that once were flushed and scoured by a changing main channel are now subject to siltation and fill at alarming rates (Ackerman, 1977; Claflin, 1977). Dredge spoil produced from the main channel maintenance activities has filled important fish spawning and nursery areas (Fish and Wildlife Management Work Group Draft Appendix, GREAT I). This habitat manipulation and degradation has resulted in a need to assess the importance of riverine habitats to fish populations. Wing and closing dams are among those habitats which have undergone a variety of changes. Wing dams are thought to be some of the best and most heavily used fish habitats along the main channel border (Robinson, 1970; Gengerke, 1978), however, little quantitative or qualitative work has been completed that assesses the importance of wing dams as fisheries habitats. To accomplish this goal, three factors need to be determined:

- 1. Location, physical characteristics, and classification of the wing and closing dams.
- 2. Sampling of wing and closing dams to determine fish usage of the areas.
- 3. The relationship between these parameters.

Once these factors have been determined, recommendations for the modification and reconstruction of training structures could be made that would meet both the hydraulic needs for the dam and also be beneficial to the river's fisheries. This project addresses the location, physical characteristics, and classification of the wing and closing dams.

METHODS AND PROCEDURES

The study area includes portions of the Upper Mississippi River Pools 9 through 19 that form Iowa's eastern border (Figure 2). The Fish Management Section of the Iowa Conservation Commission (ICC) inventoried the wing and closing dams on the Iowa side in Pools 9, 10, 12, 13, 14, 17, 18, and 19. Funding was provided by the Fish and Wildlife Management Work Group (FWMWG) of the Great River Environmental Action Team (GREAT II). The Fish Research Section of the ICC inventoried

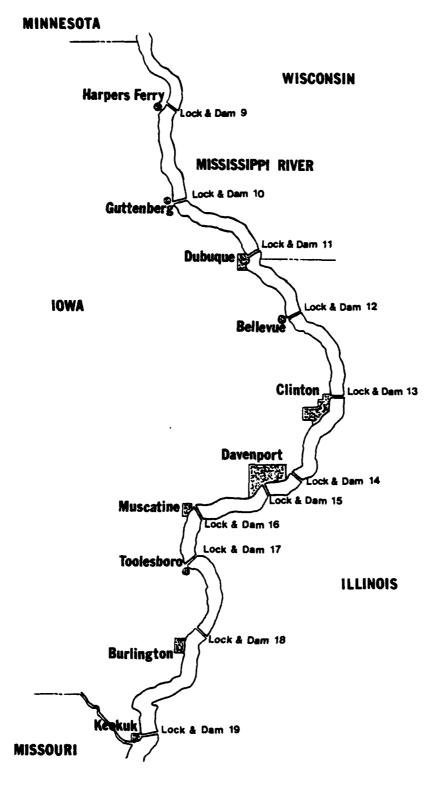

Figure 2. Towa wing dam classification study area, Upper Mississippi River Pools 9 through 19, 1979.

Iowa's wing and closing dams in Pools 11, 15, and 16 under separate funding from the National Marine Fishery Service. Field data were collected between August 27, 1979 and November 5, 1979. Data from both studies were combined for analysis.

A preliminary wing and closing dam inventory was conducted using U.S. Army Corps of Engineer (COE) records from the Rock Island and St. Paul Districts. The COE records indicated that 558 wing and closing dams had been built along the Iowa border and were numbered in the order of construction date. The COE numbering system was modified for this study and the dams were renumbered in numerical order. The first upstream dam in each pool was designated dam number one (example: The first dam in pool 9 was numbered 9-1). Dams which had been divided by sedimentation or dredge spoil islands were renumbered and inventoried as separate dam types (straight or closing). A total of 35 dams were subdivided which added 37 dams to the COE number. Subdivided dams are noted with an asterisk in the Appendix. Construction data were tabulated for the 595 wing and closing dams bordering Iowa (Appendix I). Other information tabulated included river mile, construction date, rework date, rework type, length, elevation and depth at operating pool. The type of dam (straight, L-shape, or closing) and location in the river sinuosity (inside bend, outside bend, or straight section) were also noted.

Field data were collected for each training structure. Dams which could not be located with a reasonable effort were considered eroded or covered with bottom sediments. After locating each dam a twelve foot orange pole was placed at the shore end. A Raytheon model DE 719B recording fathometer was used to locate the distal end of the training structure and a Rangematic 1000 was used to determine the dam length. A floating line was used to measure 100 feet above and 100 feet below the dam and a series of poly jugs with anchors were used to outline each sample area.

Water depths and river bottom contours were recorded using the recording fathometer. A minimum of six transects were recorded for each dam (Figure 3). Three transects (1, 2, 3) were run upstream perpendicular to the dam and three transects (A, B, C) were run parallel to the dam from the distal end to the Iowa bank (Figure 3). Effort was made to maintain a constant boat speed while mapping.

Current velocities were measured and recorded for each wing or closing dam using a Gurley model 622-E cable suspended current meter. The boat was anchored and allowed to stabilize. One minute readings were made 100 feet above (A), on (B), and 100 feet below the dam (C) (Figure 4). Current velocities were measured

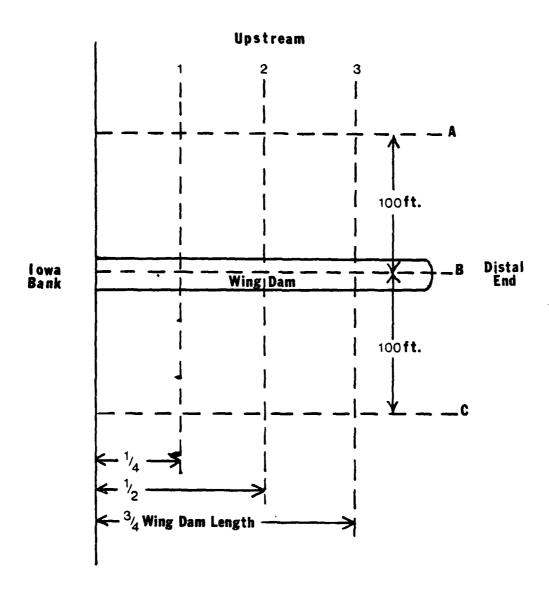

Figure 3. Transect locations for recording bottom contours of the Upper Mississippi River wing dam bordering Iowa, 1979.

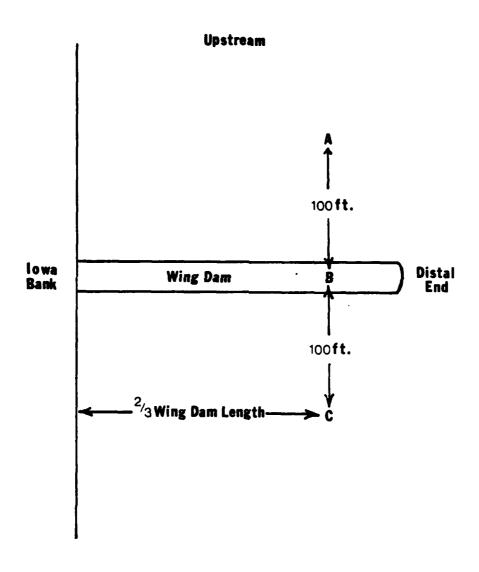

Figure 4. Sample locations for measuring current velocities on the Upper Mississippi River wing dams bordering Iowa, 1979.

2/3 the dam length from shore and 6/10 the water depth.

A standard nine inch Ponar dredge was used to collect bottom samples. A total of four samples (A, B, C, D) were collected for each dam (Figure 5). Sample locations were 100 feet upstream and 100 feet downstream at 1/3 and 2/3 the dam length. A visual percent particle size estimate was recorded for each grab (<0.62 mm-silt, 0.62 to 2 mm-sand, 2 to 250 mm-gravel, >250 mm-boulders).

Aquatic vegetation, if present, was identified as emergent or submergent and relative abundance was noted as sparse, moderate, or heavy.

After the field investigations were complete, the wing and closing dams were drawn to scale on topographic GREAT II (Great River Environmental Action Team) base maps and numbered.

RESULTS

A total of 595 wing and closing dams were inventoried on the Upper Mississippi River bordering Iowa (Table 1). Data showed that 194 (33 percent) of the structures within the study area had been completely eroded or covered with bottom sediments. An additional 23 dams (4 percent) had been physically removed by the Corps of Engineers. This equals a 36 percent loss of dams due to sedimentation or erosion and removal (Table 1).

The greatest number of wing and closing dams were constructed in Pool 11 (Table 1). The highest percent loss from sedimentation or erosion and removal was 80 percent in Pool 15 (Table 1). The lowest percent loss was 15 percent in Pool 17 (Table 1).

Corps records indicate that approximately 386,714 linear feet of wing and closing dams were constructed along the Iowa shore (Table 2). Field measurements indicate approximately 218,953 feet of the training structures remain in 1979 resulting in a net loss of 167,761 feet (43 percent) (Table 2). The greatest net loss by pool was 47,708 feet in Pool 18 (Table 2).

The mean water depth on the dams corrected to operating pool level for all pools combined was 5.5 feet (Table 3). The greatest mean depth was 8.8 feet in Pool 19 and lowest was 4.0 feet in Pool 14 (Table 3). All training structures within the study area were submergent at operating pool levels. The greatest average maximum depth within 100 feet above the structures was 15.2 feet on Pool

Table 3. Average water depth on the training structures at flat pool and the average maximum depths within 100 feet above and below the training structures by pool on the Upper Mississippi River bordering Iowa, 1979.

| d | verage depth on structure at flat pool | Average maximum depth above structure | Average maximum depth below structure |
|-----------------|--|---|---|
| 9 | 4.9 | 12.3 | 15.6 |
| 10 | 4.8 | 14.6 | 17.0 |
| 11 | 4.5 | 14.0 | 17.4 |
| 12 | 5.8 | 11.7 | 13.9 |
| 13 | 5.7 | 14.9 | 19.1 |
| 14 | 4.0 | 12.9 | 15.0 |
| 15 | 5.3 | 9.1 | 9.5 |
| 16 | 5.7 | 12.9 | 12.5 |
| 17 | 5.6 | 12.8 | 14.7 |
| 18 | 5.9 | 14.5 | 18.3 |
| 19 | 8.8 | 15.2 | 16.8 |
| Overall Average | 5.5 | 13.2 | 15.4 |

19 (Table 3). The greatest average maximum depth within 100 feet below the structures was 19.1 feet in Pool 13 (Table 3).

Sand was the dominant bottom type in all pools comprising 78.6 percent of the total substrate material collected (Table 4). The highest percent composition of sand by pool was 100 percent in Pool 15 (Table 4). Silt was the second most abundant substrate material at 14.4 percent (Table 4). The greatest percent of silt was 32.7 in Pool 14 (Table 4). Gravel was the third most abundant substrate material at 4.3 percent and boulder was the least abundant at 2.7 percent (Table 4). Gravel was most abundant in Pool 16 with 13.4 percent, with boulder most abundant in Pool 18 with 9.3 percent (Table 4).

There was no significant difference in percent composition of substrate particle size by wing and closing dam type, however, there were significant differences in substrate particle size due to location of the dam in the river's sinuosity (Table 5). Sand was the dominant substrate material collected from the dams regardless of river location (77.4 percent). However, the percent composition of the larger particles increased on the straight and outside bends of the river (Table 5).

Current velocities were taken on different days over a three month period. There were many changes in the river stage and water discharge rates during this period. It was not possible, from the data collected, to compare current velocities among dams within the pools and among pools. The highest average current velocities for all pools were recorded on the dams at 1.66 feet per second (FPS) (Table 6). The recorded average current velocities 100 feet above and 100 feet below the dams were 0.99 FPS and 1.00 FPS, respectively (Table 6).

There was no significant difference in the average water depth on the dams due to location. The average water depth on the dams varied from 5.6 feet in straight sections to 4.9 feet on inside bends (Table 7). However, there was a significant difference in the average maximum depth in the dam study area due to dam location (Table 8). The average maximum depth for all pools was greatest at 19.7 feet along dams located on outside bends (Table 8).

Aquatic vegetation was not observed at any of the sampling sites during the study period. This was probably due to the late fall field data collection dates, the relatively high current velocities measured along the dams, and the constant shifting of the river substrate materials.

Rationale for the Selection of Classification Criteria

A computer program was initially used to compare data collected. It was expected that the analysis would provide classification of the dams due to natural breaks within the system. The method used for clustering was an unweighted pair method. The program arranged the set of objects whose pairwise similarity coefficients were given into mutually exclusive homogenous subgroups and displayed the results in the form of a dendrograph. However, it became apparent that by using this analysis, the dams would not drop out into identifiable groups. The cluster analysis provided insight into the relationship among dams, but the selection criteria remained undetermined.

Consequently, in developing the classification system an attempt was made to select and limit the physical criteria to those characteristics deemed most important and over which man could exert some control. The wing and closing dams were grouped by the following criteria:

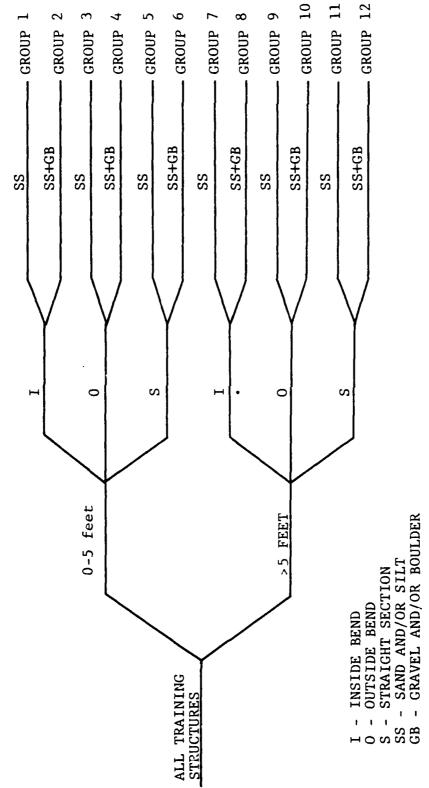

- 1. Depth of water on the dam adjusted to operating pool:
 - 0 to 5 feet
 - >5 feet
- 2. Location of training structure in relation to the river's channel:
 - I inside bend
 - 0 outside bend
 - S straight section
- 3. Substrate particle size:

SS - sand and/or silt

SS+GB - sand and/or silt plus gravel and/or boulder

These criteria provided a means of classifying the dams into twelve definable groups (Figure 6). A total of 373 wing and closing dams were sorted into the twelve groups (Table 9). A total of five wing dams were not surveyed. Wing dams 11-9 and 14-18 were emergent due to the river stage being below operating pool level. Wing dam 11-42 was located in a barge fleeting area and was inaccessible for survey work. Wing dam 12-2 was temporarily removed for bridge construction and wing dam 14-16 had a flood wall constructed over a portion of the structure.

RECOMMENDATIONS

This classification system was developed to provide a systematic sorting of the physical parameters for the wing and closing dams located along the Iowa border. This system is one of many methods which could be utilized. The considerable amount of data collected for this study could be used for the development of an expanded or refined classification system. The cluster analysis approach should be continued, but programmed to select different physical criteria in an attempt to better define the relationships among physical parameters. This classification system is, however, the first step in the process to better understand these structures and their roles as fish habitats.

Continued Wing Dam Investigations

It is recommended that the Fish Research Section of the ICC continue the wing dam investigations. The proposed study would use the data collected and the classification system developed from the present study. The proposed study objectives and methods are included in Appendix II.

ACKNOWLEDGEMENTS

I would like to acknowledge many people who gave valuable assistance throughout this study. Gary Ackerman, Bob DeCook, Al Van Vooren, Dennis Wiess, John Pitlo, Mark Anderson, Dean Beck, and Gaylen Reetz were instrumental in collecting field data. Mark Anderson, Dean Beck, and Gaylen Reetz assisted in tabulating the data, and John Pitlo contributed to the data analysis.

KEY TO APPENDIX I

IA WD N

Wing dam number assigned for this study - first number is pool in which dam is located, second number is the dam number which is numbered consecutively from north to south in each pool.

COE N

Wing dam numbers from Corps of Engineers records - first number is sheet number from original Corps maps, second number is dam number which was assigned in consecutive order by date of construction. Asterisk (*) indicates sub-divided dams which are considered as individual dams in this study.

RIVER MILE

Location of dam by river mile to closest tenth mile.

DT

Dam type. S indicates a straight dam, C is a closing dam and L is an L-shaped dam, T is a T-shaped dam.

DATE CONS

Year the dam was constructed.

REWORK YEAR

Year the dam was reworked.

REWORK TYPE

Type of work done on dam - RP indicates repair, a number that follows the RP designation is the dam length in feet that was repaired; EX indicates extension of the dam, a number that follows is the length of the extension in feet; RM without a number following indicates the entire dam was removed, a number following the RM designation is the length of dam in feet that was removed; RS indicates the dam was raised in elevation, a number following indicates the length of dam in feet that was raised; NT indicates notched and the number following is the length of the notch in feet; PD indicates the top of the dam was paved; RT indicates the top of the dam was removed, WD indicates the dam was widened.

DL

The length of the dam in feet as recorded in Corps of Engineers' records.

ELEV

Elevation of the dam in feet above sea level as shown in Corps of Engineers' records.

DEPTH OP

Depth on dam top at operating pool level - (+) number indicates height emerged to nearest tenth foot, (-) number is the depth submerged to the closest tenth foot.

SD

Month and day the dam was surveyed in 1979 by the study team - E/C indicates the dam was completely eroded or covered by bottom sediments, RM indicates the dam was completely removed.

ML

Total length of dam in feet measured by the study team.

ADJ DEPTH

Depth of water on dam measured by study team, adjusted to flat pool stage. (-) number is amount submerged in feet, (+) number indicates vertical height emerged.

LC

Location of dam in relation to river meander - S is on straight section, I is dam located on inside bend, O indicates outside bend location.

PF

Physical feature of river bottom near dam - 1 indicates no scour hole, 2 indicates scour upstream, 3 indicates scour downstream, 4 indicates scour upstream and downstream, 5 indicates silted in, 6 indicates notched with scour channel, 7 indicates scour or fill.

SUBSTRATE

Percent of substrate that is: SL - silt, SD - sand, GR - gravel, BD - boulder.

MAX DEPTH

Maximum water depth in feet - U indicates within 100 feet upstream from dam centerline, D indicates within 100 feet downstream from dam centerline.

CURRENT VELOCITY

Current velocity in feet per second - UP is 100 feet upstream of dam centerline, ON is on dam centerline, DOWN is 100 feet downstream from dam centerline.

APPENDIX II

The Fish Research Section of the ICC (Bellevue Station) will conduct a fouryear post study which will use the data acquired and wing dam classification system developed from this study. The project will be initiated during the spring of 1980. The study objectives and methods are:

TITLE: Wing Dam Investigations

OBJECTIVE(S): 1) Determine wing dam characteristics which are important to fish populations. 2) Develop a strategic plan to recommend construction and modification of wing dams which is compatible with the integrity of the fishery.

To accomplish these objectives the study will be comprised of at least four jobs.

JOB 1.

Title: Determine use of wing dams by adult fish

Objective: To determine the seasonal and diurnal use of wing dams by adult fish by determining species composition and relative abundance.

Procedures:

- 1. A minimum of 19% of the classified wing dams will be selected and samples for habitation by adult fish through a stratified selection design.
- 2. Fish sampling methods will include trammel and experimental gill nets, trap nets, and electrofishing equipment.
- 3. All fish collected will be identified by species, counted, measured, and its condition noted (especially during the spring reproduction season). If large numbers of a species are captured at a single station, length will be recorded from a randomly selected subsample.
- 4. Information collected will include relative abundance, catch-per-uniteffort, species abundance and composition, and length frequency.
- 5. Environmental parameters to be collected on each wing dam sampled include water temperature, turbidity as determined by Secchi disc, and water velocity measured at .6 of the depth upstream, downstream, and on the dam.
- 6. Determine those wing dam characteristics most conducive to adult fish use and identify seasonal and diurnal use patterns by appropriate statistical analyses.

Job 2.

Title: Use of wing dams for reproduction and by juvenile fish

Objective: Determine use of wing dams as spawning sites by adult fish species and habitation by juvenile fish for nursing activities.

Procedures:

- 1. Collection of gravid females and ripe males with gillnets, trammel nets, trap nets, and electrofishing equipment during the spawning season (April-July) will be used to estimate the importance of wing dams for reproduction.
- 2. Juvenile fish populations will be sampled with standardized meter net tows and larval fish traps at the designated wing dams for adult fish sampling.
- 3. Expected sampling regime, depending upon the distribution of the classification data and the ability to use the designated sampling methods during the time of year when current velocities, debris, and siltation are at their highest levels.

Number of wing dams to be sampled = 24

- 1 sampling period in April-May for ripe adults and juvenile fish
- 24 samples X 2 sampling regimes (adults and juveniles) = 48 samples Sampling will be repeated for May-June, and June-July for a total of 144 samples per year.
- 4. All juvenile fish captured by meter net tows and fish traps will be identified and relative abundance determined by proportion.
- 5. Environmental parameters to be collected during each sample period include water temperature, turbidity as determined by Secchi disc, and water velocity measured at .6 of the depth upstream, downstream, and on the wing dam.
- 6. Determine those wing dam characteristics most conducive to fish reproduction and larval fish use by appropriate statistical analyses.

JOB 3.

Title: Adult fish use of wing dams as determined by radiotelemetry Objective: Determine the importance of Mississippi River wing dam habitat to commercial food fish species.

Procedure:

- 1. Common commercial food fish, as determined by Job 1, will be tagged with radio transmitters to determine the extent of wing dam use and the wing dam types selected for occupancy.
- 2. Approximately 35 to 40 radio transmitters will be evenly distributed among 2 or 3 fish species. Transmitter attachment will be either internally or externally, depending upon the transmitter type, fish species, and field conditions.

- 3. Transmitters with the following minimum specifications will be used:

 1) 6 month life expectancy 2) weight within 2% of the fish body weight 3) minimum signal reception distance of .5 mile. In the event that transmitters cannot be obtained that meet the above specifications, life expectancy will be sacrificed
- 4. Fish will be tagged in the spring and contacted throughout summer and fall. In the event that contact with the fish are lost, an attempt will be made to use an airplane to relocate the fish. If transmittered fish are captured and the tag returned, every effort will be made to place the transmitter on a different fish.
- 5. Tracking will consist of searching for tagged fish 7 days each month during May-Sept., totaling 35 days. Providing time and manpower permits, some night tracking is also contemplated.
- 6. Data analyses will consist of the percent of time spent in wing dam habitats compared to other habitats. Also, the type of wing dam use will be noted.

JOB 4.

Title: Document fishermen usage and catch on wing dams

Objective: Determine the extent commercial fishermen use wing dams.

Procedure:

- 1. Document fishermen usage by direct observation and personal contact.
- 2. Determine species sought, species harvested, catch-per-effort, and amount of time spent fishing wing dam habitats.
- 3. Associate the physical characteristics of wing dams with commercial fishing and fish occupation.

RESULTS AND BENEFITS EXPECTED:

to obtain specifications 2 and 3.

This study will provide valuable information relative to the importance of wing dam habitats to fish and commercial fishing on the Upper Mississippi River. In addition, it will aid in designing and planning new hydrological navigation structures and the modification and repair of deteriorating structures.
