PRINTR:- A TEXT AND GRAPH PLOTTING SYSTEM WITH EXPANDED CAPABILITIES.

G.F. FORSYTH

ABSTRACT/SUMMARY

A system for using control character sequences to extend a printer's character set and to more efficiently handle graph data and drawings has been written as a machine language program for the PDP8 computer with electrostatic plotter. Features added to text files include Greek and mathematical symbols, superscripts, two levels of subscripts and overstruck (superimposed) bars, dots and combined bars and dots. Plot files have two modes using 8 or 12 bit data words and may be either continuous scan or byte addressed. Plot and Text files may be mixed but not superimposed.

POSTAL ADDRESS: Chief Superintendent, Aeronautical Research Laboratories, P.O. Box 4331, Melbourne, Victoria, 3001, Australia.

1 INTRODUCTION.

The ARL Transonic Wind Tunnel Dynamic Derivatives Control and Data Acquisition Equipment consists of a minicomputer (DEC 8A800), a graphics terminal (DEC VT55), a programmable data system and a electrostatic printer/plotter (VERSATEC D300A). Data and programs are stored on IBM standard (3740) flexible discs.

The processor of this system may be programmed in machine language, FORTRAN 2 or 4, or BASIC/LAES5 which is an extension of OS-8 BASIC, to fully utilize the features of the equipment ⁽¹⁾. A feature of these high level languages is their handling of data as either single characters of 6,7 or 8 bits or as precise numbers of 24, 36, or 72 bits. BASIC, for example, has only 2 classes of data: (1) numbers which have a sign and 23 binary bits (6 decimal digits) and an exponent with sign and 11 bits ($10^{\pm616}$), and (2) characters which are 6 bit ASCII. On the other hand, the Versatec Printer/Piotter has an 8 bit parallel input.

This lack of a convenient means of handling and outputting single 12 bit words, particularly to serial terminals, leads directly to the use by most graphic terminals of strings of characters to convey plot data, as such screens are normally of 8 to 9 bits resolution. These graphic data strings are usually distinguished from ASCII print data by being prefixed by an escape (033) code sequence or by a control code (8 to 37 octal in 7 bit). This latter course was chosen here to simplify use of the text processor RUNDFF and to clearly identify these files from VT55 command files which use escape codes.

As well the printer/plotter is only capable of upper case characters in the print mode. This has introduced a difficulty in both graph labels and text since the notation commonly used in aerodynamics differentiates between many upper and lower case characters e.g. I and L are roll and lift. Also, angles are referred to by lower case Greek characters such as α , β and ϕ .

Dynamic derivatives introduce the added refinement that meanings may be changed by the vertical orientation of expressions (subscripts, subsubscripts and superscripts) and particular meanings are assigned to expressions such as $C_{m_{cc}} + C_{m_{cc}}$ where the dot over the

a indicates differential with respect to time. Other superimposed or overstruck modifications to characters include the use of a bar to denote a nondimensional quantity. With an electrostatic printer and many other line printers it is not possible to overstrike, that is print two characters in the same position. Such symbols may then only be produced by a software approach to character generation.

For these recents, a machine language (PALS) program was written in July, 1979, to handle both plot and print files composed solely of character strings as plot data for the printer/plotter or any other raster scan plotter or display. Version 2A of this program, which was dated 31-AUG-79, is described here. This program is presently available⁽²⁾ from the Digital Equipment Computer User's Society (DECUS) as DECUS8-915.

Where not otherwise stated, the character codes used will conform to the standard of the American Standard Code for Information Interchange (ASCII).

2 PRINT FILES.

Normal ASCII codes do not include some of the special characters used in scientific writing and data handling. For this reason some of the standard codes have been omitted and new codes added to allow a font of 128 printable characters. Since these new characters do not appear on a keyboard, and to allow them to be handled as ASCII files, most of these extra characters are generated by prefixing standard codes with the code "control A".

The deleted codes are those represented by codes 136.174.176 and 177. These are shown on some keyboards as up arrow, vertical separator, squiggle and rubout and are printed by this program as degree, integral, partial differential and infinity (printed twice). The last two codes are not accepted by some programs but all these codes can be generated by the control A sequence. This sequence subtracts 101 octal from the transmitted code. The generated character set is contained in Table 1.

The characters in this font may be additionally modified by an overstrike font. Following a backspace the next non-backspace is treated as a 4 bit code for an overstrike. The overstrikes available are bar, dot, two dots, bar and dot, bar and two dots and hat. A space may be programmed to any other overstrike.

The first bit of the overstrike code flags the level at which it is to be printed. Lower case letters and Greek Characters include some characters which do not ascend above the fourth row and the overstrike may be moved down 3 rows to allow for these. The appropriate codes are A, B, C, D, E, F and G for the higher set and I, J, K, L, M, N and O for the lower set. The six active pairs, that is, all but G and D, produce the following result on A and α as examples:- \widehat{A} , \widehat{A} , \widehat{A} , \widehat{A} , \widehat{A} , $\widehat{\alpha}$, $\widehat{\alpha}$, $\widehat{\alpha}$, $\widehat{\alpha}$. The sequence backspace Ω produces no operation and is used to follow a backspace which is not required to generate an overstrike.

Backspace is also used as one mathod of flagging underlines. The sequences backspace/minus and backspace/underline underline the previous character. An example is +(backspace)— which produces \pm . Underlining of headings is normally done by underline characters on the next line. Such a line produces only a single plot scan.

The subscripts and superscripts are generated by two more control characters with "control N" meaning shift down and "control O" shift up. 4 levels have been provided with 1 level above the starting position and 2 below. Overstrikes and "control A" characters can be used in any level. The sequence backspace 3 mentioned above as a no operation code can be used to help load characters in different levels at the same character position. Table 2 lists the control characters identified by this program.

It should be noted that program buffer length limits the length of a line to 128 characters and that this includes any nonprinting characters between the line feeds. The exception to this is the form feed character "control L" which must appear on a line by itself.

3 PLOT FILES.

There are good reasons why plot files should be carefully designed. A single page (A4) of output is equivalent to over 93,080 bytes (8 bit) of data. If the plot file represents a direct raster scan of such a page, it occupies nearly 350 088 blocks and only 1 or 2 such pages fit on a RX01 diskette. Apart from the space problem there is the difficulty in handling such binary or save-mode files. Both Basic and Fortran 4 are capable of handling such files but only on a fixed length file and only bit by bit. In fact, Fortran 4 is harpinst with 6 bit ASCII files.

Accordingly, a scheme which can represent plot files as 6 bit ASCII files is a logical choice. Other restrictions which come out of the line handling capability of the PRINTR program include a maximum line length of 128 ASCII characters. In fact, lines should terminate with the normal carriage return/line feed combination to allow ASCII line sorting and to shorten still further the file length of plot files. Plot files will be distinguished from other ASCII files by beginning each line with a control F character. This also allows mixed files.

This leaves noon for 125 non-control characters on a line. Each character is significant only to 6 bits to this represents only 750 bits per line compared to the Versated D800A's 500 bits per line. As well, space on the line will be significantly saved if some means of leading blank expression on tabulation is devised. The first character in a line can be used to flag 8 to 63 leading blank bytes, leaving 124 characters or 744 bits in a line. These characters will be considered as pairs making 12 bit words. Several possible formats for using these words will be exumined.

If each word is the next 12 bits in a rooter scan, a line without a set pattern may be represented to 744 bits. However, a line with a single point at each end will require all 124 characters. If each 12 bits represents a hyte and a 4 bit repeat code then the full, no pattern line has only 496 bits but the line with a point at each end requires only 14 characters. Yet another variation would be to use the first bit as a flag to indicate a tabulation, the next 3 as repeat code and the last byte as either the character or the tabulation required. This would still give only 496 bits from a full line but would need only 6 characters for the end-marked line.

Perhaps the most acceptable format for graphs and diagrams however is one where words represent alternately addres as and data. This is similar to the format used by the VTSS display but with the horizontal and vertical axes into changed. This format is no more compact than the tabulation method but is more easily understood.

No single format of trose convidened has advantages in both the full line and end-morked cases. For this reason a two mode approach has been adopted in an attempt to previde as many advantages as possible.

The plot line format chosen is thus:- control F, special address word, data word, mixed data and address words to 62 words.

The special address word also sets mode to 8 or 12 bit data and all address words have the formati-

bitð	I to indicate address
bitl	1 to indicate continuation required
bit2	1 to indicata 12 bit mode
bit3	unused
bits4-11	address in bytes from start of line.
The 8 bit da	ta words have the format:-
The 8 bit day bit0	ta words have the format:- 0 to indicate 8 bit data

The 12 bit data words are all data. In the 12 bit mode only one address word is used in each line and this contains the continuation code. The mode may be changed to 12 bit only once in a line since once in 12 bit mode no mode change code is available.

In the 8 bit mode addresses may appear anywhere in a line and the continuation code may also appear m any address but would normally appear in the last word in a line. Addresses must appear in order however and must not try to backspace the output.

4 MIXED FILES.

Mixed mode print and plot files are not only possible but are the normal arrangement. Nodes may not however by mixed on the same line. This is an example of such a mixed file. The specifications of a line beginning with "control F" follow section 3 above , otherwise section 2 is the relevant description.

An example of a mixed the (with plot mode axes and print mode labels) used to produce a small figure follows.

The 12 bit mode may also be used to generate other fonts, e.g. 14 puint:-

THE END

This example illustrates a future extension of this system. If a FORTRAN or PASCAL program is written to turn PRINTR text files into plot files with 14 point main text and 10 point shifted text, and the resultant file is output by PRINTR onto noll paper and then reduced by a lineal factor of 0.7, very high quality output can be obtained. Such a system may also use proportional spacing of characters and equalization of spaces. The effective fonts are 10 point for the main and 7 point for the shifted text.

5 USING WITH RUNDFF.

The software available on this processor includes the text handler RUNNEF version 68 which is capable of formatting text files to fully utilise PRINTR. The operating procedure is as follows:-

(1) Make an ASCII file using any Editor program, TECO. EDIT. VIEDII, SDS or SCROLL. This file must include normal RUNOFF commands and the additional command ".control characters" or ".co" to allow commands to be passed to PRINTR. PRINTR uses a control character to file commands and these are ignored by RUNOFF and most editors. However, some of the characters used in control F strings to generate figures will oppear as RUNOFF flags. Also, RUNOFF miscounts lines when faced with plot data. For these reasons it may be simpler to use the figures of blank features of RUNOFF to allow room to instal the figures later.

(2) Process with RUNOFF. Respond to monitor with R RUNOFF RUNOFF echais RUNOFF V68 and calls Commond Decoder which types # enter DSK:FILE.WUxD6K:FILE.RO/U\$ where FILE is input file and \$ is altmode key. Note that default input extension is RO. (3) Instal figures using an editor, if required. (4) Call PRINTR R PRINTR #FILE

Note that default input extension here is LU and that default input device is DSK: . PRINTR uses the Command Decoder so up to 9 input files may be specified at once but output is always to the plotter. An option to append =n for n copies has been allowed for but not implemented.

It is possible to assemble a particular form of RUNDFF with default conditions such that this sequence is partly unnecessary but this sequence will always perform as expected.

6 PROGRAM LAYOUT.

This program actually consists of two distinct parts which are assembled separately and are named TEXT and FONT10 respectively. TEXT is the program itself and is fully documented in the program listing. FONT10 is the 10 point font used by this system to generate text. A change of "typeface" may be accomplished by modification of FONT10 only.

7 PERFORMANCE.

Use of a software approach to generate text fonts results in an increased time to print text files compared to a hardware character generator. However the added flexibility of the software system is a mujor advantage. Despite the comment above, it only takes 14 seconds to print this page which is equivalent to about 330 characters per second.

8 USING WITH OTHER MACHINES.

This program was written in PAL8 with all non-standard codes defined in the symbol table. The source (TEXT.PA) is extensively commented. The only processor instruction used which may not be available on earlier PDP8's is BSW=7002 which is also used combined with CLL as CLL BSW=7102. To run this program on an early PDP8 both these commands must be redefined as JMS I BSWL where BSWL is a page zero reference to a subroutine to clear the link and swap the two halves of the accumulator. (See BASIC for an example of how to do this).

The plotter commands are used only in five subroutines: three WRITE.PLOTY and CLBUFF on page zero and two others, EXIT and INIT. If the plotter or printer/plotter uses the same format of commands i.e.

done	PSKF PCLP	=6661 = 6666	-Skip on done flag -clear flag,output character,set flag when			
and	MODCNL	-6644	with AC =1 =2	Clear buffer Write buffer		
			-3	Top of form		
			-6	Set print mode		
			=7	Set plot mode		

then only a change in symbol table is required. Otherwise some or all of the five subroutines will need modification.

The other plotter parameter is plot width. The D930A is 100 decimal bytes (144 octal) wide and this is required by PLTWID in the symbol table. For plotters wider than 128 characters some difficulties may arise. The buffers for shifted text are only 128 characters long

and any attempt to output a longer line will cause overflow into the next buffer. In cases where every line starts and ends with sufficient blank spaces this may be acceptable but care must be taken if the second subscript is used as this overflowe into an ASCII buffer.

The program uses 058 only for file handling and a non-058 version would require changes on the page from 00200. Also, data files may be 7 or 8 bit ASCII and 8 bit files may have parity. Any 6 bit files would also require changes on this page. Field 1 is used solely by 058 User Service Routines (USR's) for file management so a non-058 version would require less than 4K of memory.

9 CONCLUSION.

A system for using control character sequences to extend a printer's character set and to more efficiently handle graph data and drawings has been written as a machine language program for the PDPS computer with electrostatic plotter. Features added to text files include superscripts, two levels of subscripts. Greek and mathematical symbols and overstruck (superimposed) bars, dots and combined bars and dots. Plot files have two modes using 8 or 12 bit data words and may be either continuous scan or byte addressed. Plot and Text files may be mixed but not superimposed.

The description contained in this memo refers to version 2A, dated AUGUST 1979.
