ABSTRACT

The present work is a Kalman filter study, in indirect feedback configuration, for a proposed integrated inexpensive Inertial Navigation System/Global Positioning System (I.N.S./G.P.S.).

A one nautical mile per hour, local-level, twoaccelerometer I.N.S. is used where the errors are represented by a 7 state linear model.

G.P.S. is assumed to provide four range measurements from an equal number of satellites with the best relative position among those in view.

I.N.S. error analysis showed error dependence on Schuler frequency and that it was possible to neglect Foucault modulation for navigation purposes.

The present I.N.S./G.P.S. system has been shown to be quite effective since the navigation errors are reduced quickly for both short and long term periods without any divergence.

ACKNOWLEDGEMENT

I would like to express my sincere appreciation to both my advisors, Professor D. Collins for his instruction, guidance and support during this work and Professor H. Titus for his help and his outstanding lectures on Kalman filters which stimulated my interest on this area.

I. INTRODUCTION

A. OVERVIEW OF AN INERTIAL NAVIGATION SYSTEM (I.N.S.)

A conventional gimballed inertial measurement unit consists of a platform suspended by a gimbal structure that allows three degrees of rotational freedom [Ref. 1,2,7]. The outermost gimbal can be attached to the body of some vehicle and allow that vehicle to undergo any change in angular orientation while maintaining the platform fixed with respect to some desired coordinate frame.

Gyros mounted on the platform sense the angular rate of the platform with respect to inertial space and their outputs are sent through electronics to the torque motors on the gimballed structure, commanding them to maintain a desired platform orientation regardless of the orientation of the outermost gimbal which remains fixed to the body.

Feedback control loops that keep the gyro outputs nulled, will maintain at the same time the platform fixed with respect to the inertial space. These feedback loops are such that, in practice, the platform orientation is kept essentially stable regardless of the most violent vehicle maneuvering. Additional (computed) inputs can be added to the above feedback loops to maintain some other orientation,

such as North-East-Down, corresponding to the current location of the vehicle.

Accelerometers mounted on the platform can provide the vehicle's acceleration with respect to the known set of reference coordinates. In fact, specific force is measured by the accelerometers so that local gravity must be computed and appropriately subtracted from these sensor outputs in order to obtain a measurement of actual vehicle acceleration.

The vehicle's velocity and position are obtained by integration of the above acceleration measurement signals. Attitude information as well as translational information is provided by the I.N.S.. A typical gimballed inertial measurement unit [Ref. 2] is shown in Fig. 1.

B. OVERVIEW OF THE G.P.S.

The Global Positioning System (GPS) is a satellite navigation system currently under development. It will consist, according to today's available information, of 18 satellites placed in groups of six in each of three different circular, 12 hour orbits at an altitude of 10,900 N.M. inclined 63° to the equator and spaced 120° apart.

The satellites will broadcast pseudo-random noise codes (codes P and C/A) and ephemerides on two L-band signals to users worldwide in such a way that each satellite signal can be distinguished from the others by the user. A user will

. . . second the

be equipped with a small receiver (G.P.S. user equipment) which measures the pseudo-range and pseudo-range rate from the user to the satellite.

By means of a correlator-detector the time (phase) shift between each satellite signal and the user's unsynchronized clock will be measured in his receiver to provide an indication of the range from the satellite to the user. Typically, four satellite signals may be received simultaneously by the user equipment.

The phases of the NAVSTAR/G.P.S. system are snown in Fig. 2 [Ref. 8].

C. I.N.S. OPTIMAL AIDING

Once we have available a typical inertial measurement unit, or the inertial navigation system as a whole, the question naturally arises: why does this system requires optimal aiding by other navigational sensors? The answer to this question is given in Ref. 2 and here we present the concepts only.

Due to the tight control loops supporting the I.N.S. very good high frequency information is provided. However, because of gyro characteristics, the system drifts at a slow rate so that the long term (low frequency content) of the data is poor. It is well known that all inertial systems have position errors that grow slowly with time and these errors are unbounded.

.....

As opposed to an I.N.S. which can be classed as a "one nautical mile per hour system" due to the associated position error, most other navigation aids provide very good low frequency information but subject to considerable high frequency noise, due to instrument noise, atmospheric effects, antenna oscillation, unlevel ground effects and so forth.

One would want to combine the available information from an I.N.S. and other external sources in an optimal manner if possible so that one can obtain efficient estimates of navigation parameters that are best with respect to some well defined critericn. Such an optimal approach is provided by the Kalman filter approach which is briefly discussed next.

D. KALMAN FILTER

The Kalman filter is an optimal recursive data processing algorithm located in the on-board computer or central processor that uses sampled data with sample period on the order of 5-60 seconds, to maintain estimates of approximately 60-70 state variables. The filter combines all available measurement data with prior knowledge of the system and measuring devices to produce an estimate of the system states in such a manner as to statistically minimize the resulting errors. In more easily understood terms the filter, or computer program, uses the statistical

characteristics of the errors in both the inertial navigation components and the external information providing the best estimate possible, subject to certain modeling assumptions.

The filter will act to optimize the attitude, position, and velocity information accuracy by weighting each data source heavily in the frequency ranges where it provides more accurate information, and suppressing it in the region where it is less accurate. The inertial system provides good high frequency information but it drifts slowly and therefore exhibits poor low frequency performance. On the other hand, the external aids (such as G.P.S.) generally exhibit good low frequency information but are subject to high frequency noise. Therefore, the filter will use the good low frequency external (G.P.S.) information to damp out the slowly growing errors in the inertial system.

1. Type of Filter Implementation

There are two very important aspects of implementation of a Kalman filter in conjunction with an inertial system [Ref. 2].

a) Total state space (direct) versus error state space (indirect) formulation, and

b) Feedforward versus feedback mechanizations. In the indirect formulation the errors in the I.N.S. indicated position and velocity are among the estimated variables and each measurement presented to the filter is

the difference between the I.N.S. and the external source (G.P.S.) data. The I.N.S. itself follows the high frequency motions of the vehicle very accurately, and there is no need to model these dynamics explicitly in the filter but the dynamics upon which the filter is based is a set of inertial system error propagation equations, which are relatively well developed, well behaved, low frequency, and very adequately represented as linear [Ref. 2, pp. 296].

The indirect feedback configuration is considered where the Kalman filter generates the estimates of the errors of the I.N.S. and feeds back these errors to the I.N.S. to correct it. By this configuration we use the two major advantages. First that the I.N.S. errors are not allowed to grow unchecked and the adequacy of a linear model is enhanced. Second is the fact that many of the predicted error states which at next time sample time are zero, need not be computed explicitly.

The indirect feedback configuration of the Kalman filter is shown in Figure 3. In Ref. 2 there is explicitly documented the discussion of the Kalman filter configurations and mechanizations with their advantages and more comments.

2. Assumptions

The Kalman filter can be shown to be the best filter of any possible form based on the following three

Figure 3. Indirect Feedback Kalman Filter [kef. 2]

:

ı

27

.

-

assumptions: <u>a linear system</u>, <u>white noise drivers</u>, and the <u>Gaussian distribution of noise</u>.

Although the system itself may be nonlinear, formulation of an approximate linear error state space model makes linear analysis possible. The justification for the linear model is based on two points. For the aided I.N.S. case the use of linear error state space models yields a very adequate representation. The techniques of linear system analysis are also well developed and better understood than those of nonlinear analysis.

The white noise assumption implies that the noise is not correlated in time and also has equal power at all frequencies. If, in fact, a time correlated noise is required to adequately model the system, it can be produced by passing white noise through a linear shaping filter. The system can then be modeled with an augmented state variable as a linear system driven by white noise.

Gaussianess pertains to the distribution of amplitudes of the noise and implies that at any single point in time the probability density function of the amplitude takes on the shape of a normal bell-shaped curve. The assumption of Gaussian noise amplitude is justified by the fact that the system or measurement noise is typically caused by a number of sources. It can be shown mathematically that when a number of independent random

variables are added the resultant effect is very nearly a Gaussian probability density even though the individual densities are not Gaussian [Ref. 9].

Under the above mentioned assumptions of a purely white Gaussian noise, the first two moments specify the entire shape of the density describing the noise, and the mathematics of the problem are greatly simplified.

In Appendix A, a simple example of a Kalman filter application to a radar position-aided I.N.S. is given in order to make easier the understanding of Kalman filter operation.

Finally, information about the G.P.S. satellites' geometry and their observability is given in Appendix B.

II. KALMAN FILTER EQUATIONS

A. GENERAL

The design of a Kalman filter and especially the integrated I.N.S. Kalman filter design requires extensive computer simulation. This chapter of the work is a presentation of the equations which are required not only for the mechanization of the filter but also those which are necessary to simulate the dynamics of any user (aircraft, missile).

The principal tool used for the solution of this specific and other similar problems is the very common method of covariance analysis. It is known that the covariance is a measure of the uncertainty in the knowledge of the true values of the state vector components. In this work, as the covariance matrix is concerned, the off diagonal terms are assumed to be zero initially and initial conditions on the diagonal elements are arbitrarily taken. The covariance matrix of both the system and the filter are propagated forward in time by numerical integration techniques.

The adjustment of the values of the state variables, to those of the best estimate obtained with the Kalman filter, is achieved when a control is applied to the system after

the specified update time is reached and the best estimates of the states have been determined. The square root of the individual diagonal elements of the system covariance matrix (RMS values) are plotted as a function of time to provide the performance of the filter. For this study the plots are also utilized to determine the error contribution associated with each modeled error source. Furthermore, the error statistics are propagated which means that the standard deviation of the noise value is supplied whenever a noise is required.

One attribute of covariance analysis is, that under the assumptions stated in Chapter One, i.e., the linearity and white Gaussian noise, the covariance is independent of the actual measurement values and can be computed through generating a sample sequence of measurements. And as a matter of fact this method is easier to handle and work with than the corresponding Monte Carlo type simulation.

B. SYSTEM MODEL EQUATIONS

The differential equations that describe how the inertial navigator errors propagate with time are the basic equations used in this process. These equations are formulated in a set of first order, linear differential equations, driven by white Gaussian noise for the reasons described previously in this work.

31

Linear measurements corrupted also by white Gaussian noise are made upon the actual system variables. It is furthermore assumed that the equations which represent a detailed model of the system are of the form:

 $\frac{\dot{\mathbf{x}}}{\mathbf{x}_{s}} = \mathbf{F}_{s} \frac{\mathbf{x}}{\mathbf{x}_{s}} + \mathbf{G}_{s} \frac{\mathbf{w}}{\mathbf{x}_{s}}$ (1)

where

 \underline{x}_s is an n_1 vector denoting the true state F_s is an $n_1 \ge n_1$ matrix of system dynamics G_s is an $n_1 \ge m_1$ matrix of gains

 $\frac{W}{2s}$ is an m_1 vector of white noise inputs with the characteristics of zero mean and variance:

 $E[\underline{w}(i)\underline{w}(j)^{T}] = \begin{cases} Q_{s}(i) & \text{for } i = j \\ 0 & \text{for } i \neq j \end{cases}$ (2)

where the indices i and j are instants in time.

The observations which are obtained from external references and in our case of study from the G.P.S. can be described by the following linear measurement vector equation:

$$\mathbf{z}_{s} = \mathbf{H}_{s} \mathbf{x}_{s} + \mathbf{v}_{s} \tag{3}$$

where:

 z_s is a q vector of measurements

 H_s is a q x n₁ matrix of measurements

 \underline{v}_s is a q vector of white noise inputs with the characteristics of zero mean and variance:

 $E[\underline{v}(i)v(j)^{\Gamma}] = \begin{cases} R_{s}(i) & \text{for } i = j \\ 0 & \text{for } i \neq j \end{cases}$ (4)

A further assumption for the study is that the system noise w and the measurement noise v are uncorrelated for all time, i.e.,

 $\Xi[\underline{w}(i)\underline{v}(j)^{T}] = 0 \quad \text{for all } i,j \quad (5)$

C. FILTER EQUATIONS

The equations discussed above are assumed to be a complete and accurate mathematical description of the G.P.S. aided inertial navigation system dynamics and measurement equations for the purpose of simulation. They also constitute a set of equations which would be utilized in the design of a fully optimal Kalman filter.

In our case of study as also in general a suboptimal or reduced order filter design is obtained by reducing the dimension of the state vector due to the computational burden of the fully optimal filter. The states that are
eliminated are those that affect the accuracy the least of the mathematical description of the aided-I.N.S. The designed suboptimal filter can be implemented with the onboard computer (aircraft or missile).

The equations which describe the suboptimal filter are of the form:

$$\underline{\dot{x}}_{f} = F_{f} \underline{x}_{f} + G_{f} \underline{w}_{f}$$

where

$$\underline{x}_{f}$$
 is an n_{2} vector
 F_{f} is an $n_{2} \times n_{2}$ matrix of filter dynamics
 G_{f} is an $n_{2} \times m_{2}$ matrix of gains

 \underline{w}_{f} is an m vector of white noise inputs with the characteristics of zero mean and variance:

$$E[\underline{w}_{f}(i)\underline{w}_{f}(j)^{T}] = \begin{cases} Q_{f}(i) & \text{for } i = j \\ 0 & \text{for } i \neq j \end{cases}$$
(6)

The equation for the filter measurement is:

$$\underline{z}_{f} = \underline{H}_{f} \underline{x}_{f} + \underline{v}_{f}$$
(7)

where:

 $\frac{2}{2}$ is a q vector

 H_{f} is a q x q matrix of measurements

 $\frac{v_f}{f}$ is a q vector of white noise inputs with the characteristics of zero mean and variance:

$$E[\underline{v}_{f}(i)\underline{v}_{f}(j)^{T}] = \begin{cases} R_{f}(i) & \text{for } i = j \\ 0 & \text{for } i \neq j \end{cases}$$
(8)

The filter propagation and update equations based on the above models are then given below.

At measurement times (update):

$$K_{f} = P_{f} H_{f}^{T} [H_{f} P_{f}^{-} H_{f}^{T} + R_{f}]^{-1}$$
(9)

$$P_{f}^{\dagger} = P_{f}^{\dagger} = K_{f} H_{f} P_{f}^{\dagger}$$
(10)

$$\hat{\underline{x}}_{f}^{+} = \hat{\underline{x}}_{f}^{-} + \underline{x}_{f} [\underline{z}_{s} - \underline{H}_{f} \hat{\underline{x}}_{f}]$$
(11)

and between measurements (extrapolate):

$$\hat{\mathbf{x}}_{\mathbf{f}} = \mathbf{F}_{\mathbf{f}} \hat{\mathbf{x}}_{\mathbf{f}} \tag{12}$$

$$\dot{P}_{f} = F_{f}P_{f} + P_{f}F_{f}^{T} + G_{f}Q_{f}G_{f}^{T}$$
(13)

where:

 $\hat{\mathbf{x}}_{\mathbf{f}}$ is an n₂ vector denoting the best estimate P_f is the covariance matrix of the filter K_f is the matrix of Kalman gains \underline{z}_s is a q vector of the actual values of the measurements taken

+ superscript indicates the time instant just after update

- superscript indicates the time instant just prior to update

T superscript denotes the transpose matrix or vector superscripted.

The filter subtracts from the actual taken measurement \underline{z}_s the best prediction of its value before the actual measurement is taken, i.e., the value of $H_f \hat{\underline{z}}_f$. This difference is then passed through an optimal weighting matrix K_f and used to correct $\hat{\underline{x}}_f$, the best prediction of the state at the time instant before the measurement is taken. This process gives the best estimate after update. This estimate is propagated to the time of the next measurement sample according to equations (12) and (13).

The above recursive relationships are solved based on initial conditions of an assumed Gaussian density which describe the a-priori knowledge of the state as:

$$\hat{\mathbf{x}}(0) = \hat{\mathbf{x}}_{0} \tag{14}$$

and $P(0) = P_0$

The Kalman filter conditioned on the actual measurements taken, propagates the conditioned probability density of the desired states. The probability density function of a Gaussian noise amplitude takes on the shape of a normal bell-shaped curve. The assumption of Gaussian noise amplitude is well justified by the fact that a system or measurement noise is typically caused by a number of small sources and according to the Central Limit Theorem it can be shown mathematically that when a number of random variables are added together, the summation is a random variable whose density is nearly a Gaussian probability density, regardless of the shape of the densities of the individual random variables. Furthermore, the use of Gaussian densities makes the mathematics easier to handle and tractable. It is known that a Gaussian density is completely determined by its first and second order statistics, i.e., the mean and the variance. Thus, the Kalman filter, which propagates the first and second order statistics, includes all information contained in the conditional probability density mentioned above [Ref. 2: pp. 3-9].

The mean of a density function or its expectation μ , is defined as

$$E[x] = \mu = \int_{-\infty}^{\infty} xf(x) dx \qquad (16)$$

and it is interpreted as the weighted average of the values of x, using the probability density function f(x) as the weighted function. All the Gaussian white noise inputs in this study are assumed to have zero mean.

The variance of a density function, or the square of the standard deviation σ , is defined as:

$$Var[x] = \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx$$
 (17)

and it is interpreted as the weighted average of the values of $(x - u)^2$; thus, σ^2 is a measure of the density spread and a direct measure of the uncertainty since the larger σ is, the broader the probability peak is, spreading the probability weight over a larger range of x values. For the example of Gaussian density, 68.3% of the probability weight is contained within the band of σ units to each side of the mean u, which represents the area under the normal bellshaped curve between the values of $-\sigma$ and $+\sigma$ and 95.4\% of the probability weight is contained between the values of -2σ and $+2\sigma$. Since in this study vectors are used instead of scalars, the above equations (16) and (17) which give the first and second order statistics respectively for the scalar case, must be extended for the vector case as follows:

$$E[\underline{x}] = \underline{\mu} = \int_{-\infty}^{\infty} \dots \int_{-\infty}^{\infty} \underline{x} f(\underline{x}) dx_1 \dots dx_n$$
(18)

$$\operatorname{Cov}[\underline{x}] = P = \int_{-\infty}^{\infty} \dots \int_{-\infty}^{\infty} (\underline{x} - \underline{\mu}) (\underline{x} - \underline{\mu})^{T} f(\underline{x}) dx_{1} \dots dx_{n}$$
(19)

39

. . . .

•=========

III. I.N.S. ERROR ANALYSIS

A. GENERAL

One general approach to determine the navigation error caused by individual sources of error is to simulate the inertial-navigation-system nonlinear equations and sources of error and compare the navigation outputs with the simulated true position--the differince being the navigation error. However, this is not the approach used here. Assuming that the position errors are small compared with earth radius, that the velocity errors are small compared with orbital velocity, and that the alignment errors are small compared with 1 radian (or 3437 arc-min) it can be demonstrated that the propagation of errors in an inertial navigation system is very accurately governed by a set of corresponding linear differential equations. Therefore, most inertial-navigation-system error analyses are conducted working directly with a set of linear error differential equations.

Sets of error equations have been developed for various I.N.S. configurations in the context of a particular application. As a consequence, many sets of I.N.S. error equations have been developed for the various broad classes

of mechanization such as local level, space stabilized, wander azimuth, free azimuth, strapdown, etc.

The choice of navigation error variables for analysis has often followed from the coordinate system used in the navigation equations or that implied by the physical I.N.S. platform orientation. Regardless of the differences in the sets of equations the fact is that I.N.S. error propagation is to a large extent, completely independent of system mechanization. Britting [Ref. 2] has shown that the basic error differential equations for any I.N.S. may be written in standard coordinates, regardless of the physical mechanization or internal navigation variables. Furthermore, the unforced (homogeneous) portion of these differential equations is, under certain very broad assumptions, identical for any arbitrarily configured terrestrial I.N.S.

The error equations presented in this chapter follow the philosophy of [Ref. 2] including the choice of north-slaved coordinates for the error variables and the identification of the unforced (homogeneous) portion of the differential equations that is independent of system mechanization. Two of the differences that are noticeable are:

1) The error equations are written as a system of nine first order equations (and further on reduced to seven) rather than three second order plus three first order

equations. The first-order form is the state space representation of the error equations used in modern estimation theory.

2) The form of altitude compensation assumed in [Ref. 2] is not found in most inertial navigators. Gravity is assumed computed as a function of the inertial system indicated position.

B. GENERAL I.N.S. ASSUMPTIONS

The assumptions pertaining to the general error differential equations are broad enough to encompass all of the important I.N.S. configurations [Ref. 2].

1) Three accelerometers are available to measure the specific force vector. The equations for a two-accelerometer local level system are the same provided the inertialaltitude and vertical-velocity equations are deleted.

2) The accelerometers are mounted on a platform whose angular velocity is either controlled (as with gyrostabilized gimbaled platforms) or is measured (as with the strapdown systems).

3) The system's indicated velocity vector and threedimensional indicated position are obtained by integration of the gravity field compensated specific force measurements, using a correct set of differential equations.

4) A model of the earth's gravity field is used to calculate the gravity vector as a function of the system-indicated position.

5) External altitude information and other navigation measurements may be used to update the inertial-navigationsystem indicated position, velocity, and attitude.

6) A computer is available to process the navigation information and the computation errors are eitner negligible or may be treated as equivalent instrument uncertainties.

7) Both the mechanical coordinate frame (the frame tracked by the platform) and the computation frame (the frame to which the specific force measurements are transformed for velocity and position integration) are arbitrary.

C. LOCAL-LEVEL TERRESTRIAL NAVIGATOR

Many inertial navigators do use a local-level coordinate system for the velocity and position integration. The local-level terrestrial navigation system physically instruments the local geographic coordinate frame. The platform axes are commanded into alignment with the local north-eastdown coordinate system.

The local-level terrestrial system is undoubtedly the most successfuly of all inertial-navigation-system configurations. The class of local-level systems today constitutes the majority of operational inertial navigations systems. Since this system is described in detail in [Ref. 2] here are listed some of its advantages:

1) The computation of gravity components is greatly simplified. In fact some navigators use zero for both horizontal components of gravity.

2) Some inertial navigators have no vertical accelerometer (this is the case in the present study) and do not mechanize a vertical channel. The horizontal velocity and position equations of a local-level set are appropriate for such a navigator.

3) The well-known altitude and vertical velocity instability of a pure inertial navigator must be stabilized by means of an external altitude reference. But a locallevel set of variables includes altitude and vertical velocity explicitly. The altitude stabilization equations therefore can be simplified.

4) The calculations required to provide navigation outputs and displays in geographic coordinates are simplified.

D. THE TWO ACCELEROMETER LOCAL-LEVEL SYSTEM

Many inertial navigators have only two accelerometers after the vertical accelerometer has been eliminated. The system is composed of a three axis inertial platform, two accelerometers which are nominally orthogonally mounted in the instrumented east and north directions and a computer which performs the necessary navigational computations [Ref. 2].

The north and east gyros are respectively connected with the instrumented north and east accelerometers at the signal level and the gyros are torqued at a rate proportional to the vehicle's longitude and latitude rates so that the platform can maintain its axes aligned with geographic axes since the vehicle carrying the navigation system is assumed to move freely over and above the earth. The accelerometer outputs provide these required torquing signals which must be so compensated that gyro command can be obtained as a function of only the north and east velocity rates.

Such a two-accelerometer local-level I.N.S. has seven state variables: two of position, two of velocity, and three of platform alignment.

1. Error Model Equations

The general model of local-level inertial navigation systems is given by the following matrix equations:

$$\mathbf{A}\mathbf{X} = \mathbf{q} \tag{20}$$

where

A = system characteristic matrix, same for all I.N.S. configurations

$$\mathbf{q} = \mathbf{forcing} \ \mathbf{vector} \ \mathbf{of} \ \mathbf{inertial} \ \mathbf{system} \ \mathbf{errors}$$

or $\mathbf{q} = [q_1, q_2, q_3, q_4, q_5, q_6,]^{\mathrm{T}}$ (21)

 \underline{x} = error state vector of attitude, position, and velocity errors

or
$$\underline{x} = [\varepsilon_N, \varepsilon_E, \varepsilon_D, \delta L, \delta 1, \delta h]^{\perp}$$
 (22)

It is quite important to emphasize that a computer simulation program developed in accordance with the above equation (20) is valid for all possible I.N.S. configurations, space stabilized, strapdown, wander-azimuth and not only for the local-level one. Both the coordinate frame mechanized by the inertial instruments and the computation frame are completely arbitrary. It is only the forcing function, q, which depends on the system configuration through the angular velocity and orientation of the inertial instruments.

In order to rewrite this equation as a first order vector-differential equation the error state of the I.N.S. is defined as [Ref. 2]:

$$\varepsilon^{\perp}(t) = [\varepsilon_{N}, \varepsilon_{E}, \varepsilon_{D}, \delta L, \delta l, \delta \dot{L}, \delta \dot{l}, \delta h, \delta \dot{h}]$$
 (23)

and for the case of this study for two-accelerometer locallevel I.N.S. system this reduces to:

 $\varepsilon^{T}(t) = [\varepsilon_{N}, \varepsilon_{E}, \varepsilon_{D}, \delta L, \delta l, \delta \dot{L}, \delta \dot{l}]$ (24)

where the seven basic I.N.S. errors are:

 ϵ_{N} , ϵ_{E} , ϵ_{D} = north, east, down platform tilt errors δL , δl = latitude, longitude position errors

$$F_{57} = 1$$

$$F_{62} = -f_D/r$$

$$F_{63} = f_E/r$$

$$F_{64} = -i(i + 2\omega_{ie})\cos 2L$$

$$F_{67} = -\lambda \sin 2L$$

$$F_{71} = f_D/r \cos L$$

$$F_{73} = -f_N/r \cos L$$

$$F_{74} = i \tan L + 2\lambda L$$

$$F_{76} = 2\lambda \tan L$$

$$F_{77} = 2 \ln L$$

.

$$\underline{s}$$
 = 7 x 1 error vector matrix

where

$$\underline{\mathbf{e}} = [\mathbf{e}_{N}, \mathbf{e}_{E}, \mathbf{e}_{D}, \delta \mathbf{L}, \delta \mathbf{l}, \delta \mathbf{\dot{L}}, \delta \mathbf{\dot{l}}]^{T}$$

 $\mathbf{G}_{\mathbf{e}} = 7 \times 5$ forcing matrix, with non-zero elements
 $\mathbf{G}_{11} = 1$
 $\mathbf{G}_{22} = 1$
 $\mathbf{G}_{33} = 1$

47

.

δĹ, δĺ = latitude, longitude rate errors

The above statements allow equation (20) to be written as:

$$\dot{\mathbf{e}} = \mathbf{F}_{\underline{e}\underline{e}} + \mathbf{G}\mathbf{e}\underline{\mathbf{q}}$$
 (25)

where:

$$F_{z} = 7 \times 7 \text{ error matrix with non-zero elements}$$

$$F_{12} = -\lambda \sin L$$

$$F_{13} = L$$

$$F_{13} = L$$

$$F_{14} = -\lambda \sin L$$

$$F_{17} = \cos L$$

$$F_{21} = \lambda \sin L$$

$$F_{23} = \lambda \cos L$$

$$F_{26} = -1$$

$$F_{31} = -L$$

$$F_{32} = -\lambda \cos L$$

$$F_{34} = -\lambda \cos L$$

$$F_{37} = -\sin L$$

$$F_{46} = 1$$

$$G_{64} = 1/r$$

 $G_{75} = 1/r \cos L$

and $\underline{q} = 5 \times 1$ forcing vector matrix

where

$$\underline{q} = [a_1, a_2, a_3, a_4, a_5]^T$$
 (28)

and neglecting both gyro and accelerometer non-orthogonality errors the forcing functions are comprised of 10 I.N.S. component errors as below:

$$\begin{bmatrix} q_{1} \\ q_{2} \\ q_{3} \end{bmatrix} = C_{p}^{n} \begin{bmatrix} (u) \omega_{N} \\ (u) \omega_{E} \\ (u) \omega_{D} \end{bmatrix} + C_{p}^{n} \begin{bmatrix} r_{N} & 0 & 0 \\ 0 & r_{E} & 0 \\ 0 & 0 & r_{D} \end{bmatrix} = \omega_{1p}^{p}$$

$$\begin{bmatrix} q_{4} \\ q_{5} \\ 0 \end{bmatrix} = C_{p}^{n} \begin{bmatrix} (u) f_{N} \\ (u) f_{E} \\ 0 \end{bmatrix} + \begin{bmatrix} g \\ n_{g} \\ 0 \end{bmatrix}$$
(29)

where for our study of two accelerometer local-level system the platform-to-navigation transformation matrix C_p^n and the I.N.S. platform torquing rate \underline{w}_{ip}^p are as below:

$$c_{p}^{n} = I$$
, $\underline{\omega}_{ip}^{p} = \begin{bmatrix} \dot{\lambda} \cos L \\ -\dot{L} \\ -\dot{\lambda} \sin L \end{bmatrix}$ (30)

$$\underline{\mathbf{q}} = \begin{bmatrix} \mathbf{q}_{1} \\ \mathbf{q}_{2} \\ \mathbf{q}_{3} \\ \mathbf{q}_{4} \\ \mathbf{q}_{5} \end{bmatrix} = \begin{bmatrix} (\mathbf{u}) \boldsymbol{\omega}_{N} + \mathbf{r}_{N} \boldsymbol{\lambda} \cos \mathbf{L} \\ (\mathbf{u}) \boldsymbol{\omega}_{N} \\ (\mathbf{u}) \boldsymbol{\omega}_{N} \\ (\mathbf{u}) \boldsymbol{\omega}_{N} \\ (\mathbf{u}) \boldsymbol{\omega}_{D} - \mathbf{r}_{D} \boldsymbol{\lambda} \sin \mathbf{L} \\ (\mathbf{u}) \mathbf{f}_{N} - \boldsymbol{\xi}_{g} \\ (\mathbf{u}) \mathbf{f}_{E} + \mathbf{n}_{g} \end{bmatrix}$$
(31)

2. Error Equations Solution

The solution of the differential equations represented by equation (25) gives the error response for the two-accelerometer local-level navigator for arbitrary vehicle motion within the constraints implied by a "firstorder" analysis. Since the coefficients of the differential equations are time varying the analytic solution of equation (25) would be quite tedious and require the user of a computer program to generate flight profiles. In our study specific cases are examined so that the coefficients of the differential equations can easily be calculated.

The specific cases which are examined are the following three:

1) Stationary case, where $\lambda = \omega_{ie}$ and L=L=l=l=h=h=0

2) Easterly flight at 600 "ft/sec" or 355.5 "knots," where $\dot{\lambda} = 1.557 \times \omega_{10}$

3) Westerly flight at 600 "ft/sec" or 355.5 "knots," where $\dot{\lambda} = 0.442 \times \omega_{ie}$

Writing the equation (25) in terms of the error states explicitly we have the following system of differential equations which must be solved simultaneously:

 $\dot{x}(1) = -\dot{\lambda}(\sin L)x(2) - \dot{\lambda}(\sin L)x(4) + (\cos L)x(7) + q_1$ $\dot{x}(2) = \dot{\lambda}(\sin L)x(1) + \dot{\lambda}(\cos L)x(3) - x(6) + q_2$ $\dot{x}(3) = -\dot{\lambda}(\cos L)x(2) - \dot{\lambda}(\cos L)x(4) - (\sin L)x(7) + q_3$ $\dot{x}(4) = x(6)$ $\dot{x}(5) = x(7)$ $\dot{x}(5) = x(7)$ $\dot{x}(6) = \frac{g}{r}x(2) - \dot{\lambda}(\sin 2L)x(7) + q_4$ $\dot{x}(7) = -\frac{g}{r(\cos L)}x(1) + 2\dot{\lambda}(\tan L)x(6) + q_5$ (32)

The values of the parameters used for the computer simulation are given in Table II.

a. Constant Gyro Drift Errors

Letting constant gyro drift be the sole error source in the I.N.S. system where the constant gyro drift rates $(u)_{\omega_N}$, $(u)_{\omega_E}$, $(u)_{\omega_D}$ are associated with the north, east, and azimuth gyros respectively, computer simulation verfied the following.

TABLE I	I
---------	---

COMPUTER SIMULATION PARAMETERS

45°L Geographic Latitude, L 0⁰ (Greenwich) Terrestrial Longitude, 1 Earth Rate, wie 0.2618 Rad/hour Constant Gyro Drift • North, (u)ω_M 1 meru (1)• East, (u)wg 1 meru • Azimuth, $(u)\omega_{D}$ 1 meru Constant Accelerometer Bias • North, $(u) f_{M}$ 200µg (2)• East, $(u)f_{r}$ 200µg Initial Platform Tilt • North, $\epsilon_{\rm M}(0)$ 0.14 mrad • East, $\epsilon_{F}(0)$ 0.14 mrad • Azimuth, $e_{\gamma}(0)$ 0.14 mrad Initial Latitude Error, \$L(0) 0.17 mrad (3)Initial Longitude Error, 81(0) 0.17 mrad Initial Latitude Rate Error, $\delta \dot{L}(0)$ 0.34 mrad (4) Initial Longitude Rate Error, \$1(0) 0.34 mrad $\dot{\lambda} = \omega_{ie}$ Stationary Flight Constant Easterly Flight at 600 ft/sec $\lambda \approx 1.557 x \omega_{iP}$ $\dot{\lambda} = 0.442 x \omega_{ie}$ Constant Westerly Flight at 600 ft/sec Gravitational Acceleration Constant $g = 32.2 \, ft/sec$ Earth Radius r = 6,378.3 Km

 The RMS gypo drift of 1 meru corresponds to 0.015[°]/hr or 0.2618x10[°] rad/hr.

The RMS accelerometer bias of 200µg corresponds to 0.4356x10⁻³ raj/(hr)².

^{3.} The RMS position error of 0.17 mrad corresponds to 1085m or 0.586 arc min.

^{4.} The RMS velocity error of 0.34 mrad corresponds to 2 ft/sec.

For the stationary case we observe in Figures 4 through 10 that for the north and east level errors, ϵ_N and ϵ_E , the Foucault modulation is an effect of first-order in contrast with the latitude, longitude and azimuth errors 6L, δ 1, and ϵ_D respectively where the Foucault modulation has only a second-order effect [Ref. 1]. These computer solution results suggest that it would be convenient, for design purposes, to neglect the Foucault modulation since the equations we obtain then are easily solved and give solutions with approximately the same amplitude information for latitude and longitude which are of primary importance for navigational purposes while the relatively poor information of the level errors is of secondary importance.

We further note from these computer graph solutions that the effect of the Foucault terms in the error equations system, is to modulate the Schuler oscillations at a frequency given by the local vertical projection of earth rate, namely $\omega_{ie} x \sin L$, which corresponds to a period of 33.9 hours for the selected latitude $L = 45^{\circ}$.

For the case of constant easterly flight at 600 ft/sec the results are given in Figures 11 to 17. Comparison with the curves for the stationary case indicates that the lowest modulation frequency has increased from $\dot{\lambda} = \omega_{ie}$ to $\dot{\lambda} = 1.557 \times \omega_{ie}$ and the space rate period is 10.9 hours while the Foucault modulation now occurs with a period of

about 21.8 hours instead of the 33.9 hours period for the stationary case.

Another important feature revealed by the above comparison is that the azimuth and latitude errors are reduced from the corresponding for the stationary case by a factor of 1.557 which represents the ratio λ/ω_{ie} for this case.

For the responses to the north and azimutn zero drift, $(u)\omega_N$ and $(u)\omega_E$, the vehicle motion appears to have little effect on the error growth in the cases that exhibit a longitude error which grows with time.

The level errors in response to level gyro drift are seen to remain unchanged while the level error response to azimuth gyro drift, $(u)\omega_D$, is seen to emerge from the computer noise having a peak value of 2.3 rad/meru (Figure 13).

The longitude error in response to azimuth gyro drift which was bounded for the stationary case is now reduced by the factor λ/ω_{ie} or by 1.55 while the latitude and longitude rate error magnitudes are unaffected by the vehicle motion.

Finally for the westerly flight case it is verified that the level errors remain unchanged without the effect of Foucault modulation, but the latitude, longitude, and azimuth errors grow approximately in proportion to the

time-drift rate prodct. The computer solution graphs for the westerly flight case are shown in Figures 19 through 24.

Similar results are found for the cases of east and azimuth gyro drift but they are not included here due to large amount of graphs.

b. Accelerometer Bias Errors

Considering the accelerometer bias as the sole error source computer simulation of equations (25) shows the following result of the effects of the north and east accelerometer bias, $(u)f_N$ and $(u)f_E$ respectively, on the navigation and level errors.

For the stationary case the results are shown in Figures 25 through 31. We note that the Schuler mode is predominant since the accelerometer bias directly excites the relatively high gain level loops and that the Schuler oscillations are modulated at the Foucault mode frequency of 33.9 hours per cycle. The maximum values for the navigation errors proved to be in the range of 20 x 10^{-7} rad/200 µg for the latitude error and 1.4 x 10^{-6} rad/200 µg for the longitude error.

we notice as for the constant gyro drift case that we can neglect the effects of Foucault modulations as first-order ones and proceed in the solution of the resulting equations more easily obtaining almost the same approximate amplitude information of the navigation and level errors.

For the case of constant easterly flight at 600 ft/sec the computer simulation graphs are shown in Figures 32 through 38. We observe here that again the Foucault modulating frequency has increased by a factor of 1.55 which corresponds to the ratio i/ω_{ie} . Nevertheless we see that the error sensitivities remain unchanged with the previously explained stationary case.

Figures 39-45 show computer solutions of the navigation and level errors for the case of westerly flight at 600 ft/sec.

We see now that the Foucault modulating frequency has decreased by a factor 0.442 corresponding to the ratio i/ω_{ie} in this case and once again we can proceed to the solution of the equations without considering the Foucault terms, especially for design purposes. An easy extension of the above observations is that for the limiting case when the terrestrial longtitude rate, 1, in a western direction is equal to the earth rate, ω_{ie} , then the Foucault modulation disappears completely leaving a pure Schuler oscillation.

c. Initial Condition Errors

The results on the navigation and level errors due to effects of the initial conditions are now presented accompanied by only the most important graphs of the

computer simulation since the total amount of graphs is too large to be included in this study.

For the stationary case selected graphs representing the level errors for an initial north, east and azimuth level error of 0.14 mrad or 0.438 arc-min are shown in Figures 46-47, 43-49, and 50-51 respectively.

Figures 52 through 57 present the level and navigation errors for an initial latitude rate error of 2 ft/sec corresponding to 0.34 mrad/hour while figures 58 through 63 show the associated errors with an initial longitude rate error of the same amount.

There is no need to include any graphs for the resulting errors due to initial longitude error since by inspection of the error differential equations we can see that longitude is uncoupled from the other computation loops so that an initial longitude error holds constant and no other error becomes non-zero.

We discussed up to now the errors of a pure I.N.S. system. In the next chapter we proceed with the consideration of the combined I.N.S./G.P.S. system and the results we achieved after computer simulation.

IV. I.N.S./G.P.S. SYSTEM MODEL AND EQUATIONS SOLUTION

In order to apply the Kalman filter equations discussed in Chapter II a reference system model which is a good approximation to the real world dynamics is needed.

In this chapter we outline the reference I.N.S./G.P.S. system equations selected for this study. First we are defining the error states incorporated in the system model along with their assumed initial conditions values. Next we discuss the modeling of the I.N.S. plant error states and finally we present the equations for the integrated I.N.S./G.P.S. system together with their simulated computer results.

A. SYSTEM MODEL

1. State Variable Definition and Initial Conditions

In Table III we present a listing of the state variables utilized in the reference system model. The initial conditions on the I.N.S. error states are highly arbitrary and the selected values are similar to those used in other unclassified studes [Refs. 4,5].

For the initial conditions on the gyro error states and the accelerometer, the values are selected for a typical inertial navigation system of one nautical mile per hour class.

After the above definition of the initial conditions we have by the same time specified in a complete way the initial covariance matrix P(0), since its diagonal elements are the squared values of the given RMS initial conditions. The remaining off-diagonal elements of the initial covariance matrix are assumed to be zero initially.

Furthermore the propagation of the linear variance equation (13) requires an additional knowledge of the two matrices F and Q* where:

$$Q^* = GQG^{\mathrm{T}}$$
(33)

where

G is the forcing input matrix

Q is the input noise covariance matrix

and the F matrix is the same as in Equation (25) and which has been used in the previous chapter for the inertial navigation system error equations solution and computer simulation.

For the Q* matrix the only non-zero elements are all diagonal and we will denote these from now on as Q_i where the subscript i denotes the row and column of the value. For example, Q_3 indicates that this is the value which belongs to the intersection of the 3rd row and the 3rd

column in the Q* matrix and corresponds to a white noise input on state variable number 3.

These non-zero elements in the reference system Q^* matrix are five, corresponding to state numbers 1, 2, 3, 6 and 7 according to the notation of Table III.

2. Plant Error States

The following seven states, North, East, and Azimuth level errors, X and Y position errors, X and Y velocity errors, constitute the plant error states. The differential equations of these states describe the natural unforced dynamic response of the errors in the inertial navigation system.

There are various models for the implementation of these error states. As we did in the previous chapter we will use again the Pinson error model described by the matrix F given in equation (25) for our specific case of the local-level two-accelerometer inertial navigation system configuration.

B. EQUATIONS SOLUTION AND COMPUTER SIMULATION

Using the definitions described in previous pages we can write the following equations for the error states:

$$\underline{x}(t) = \underline{F} \underline{x}(t) + \underline{G} \underline{w}(t)$$

$$z(t) = H x(t) + v(t)$$
(34)

TABLE III

I.N.S./G.P.S. SYSTEM STATE VECTOR DEFINITION

Error State	Symbol	Definition RM	IS Initial	Condition
		I.N.S. PLANT ERROR STATE	S	
1.	ε _N	North atttiude error	0.14×10^{-3}	Rad
2.	εΞ	East attitude error	0.14x10-3	Rad
3.	ε _D	Azimuth attitude error	0.14×10^{-3}	Rad
4.	δĹ	Y position error	0.17×10^{-3}	Rad
5.	5 1	X position error	0.17×10^{-3}	Rad
6.	۶Ľ	Y velocity error	0.34×10^{-3}	(2) Rad/hour
7.	δĺ	X velocity error	0.34×10^{-3}	Rad/hour
		I.N.S. ERROR SOURCES		
8.	(u) w _N	North Gyro Drift	1 meru	(3)
9.	(u) _w E	East Gyro Drift	1 meru	
10.	(u) w _D	Azimuth Gyro Drift	1 meru	
11.	(u)f _N	North Accelerometer Bias	200x 10 ⁻⁶ g	(4)
12.	(u)f _E	East Accelerometer Bias	200x10 ⁻⁶ g	

^{1.} The RMS position error of 0.17 milliradians correponds to 1085m or 0.586 arc min.

The RMS velocity error of 0.34 millirad/hour corresponds 2. to 2 ft/sec.

The RMS gyro drift of 1 meru corresponds to $0.015^{\circ}/hr$ or 261.8x10[°] rad/hour. The RMS accelerometer bias of $200x10^{-6}g$ corresponds to $0.4356x10^{-3}$ rad/(hr)². 3.

^{4.}

where

- $\underline{x}(t) = 7 \times 1 \text{ error state vector}$ = $[\epsilon_N, \epsilon_E, \epsilon_D, \delta L, \delta l, \delta \dot{L}, \delta \dot{l}]^T$
- \underline{F} = 7 x 7 Pinson error model matrix as described in equation (25)
- \underline{G} = 7 x 5 input forcing matrix as described in equation (25)

 $z(t) = 2 \times 1$ vector of measured states

H = 2 x 7 measurement matrix where

<u>H</u> =	0	0	0	1	0	0	0
	0	0	0	0	1	О	оJ

denoting that we have available measured information for the X and Y position error.

 $\underline{w}(t) = 5 \times 1$ forcing vector assumed to be white Gaussian noise

and

 $\underline{v}(t) = 2 \times 1$ vector of measurements noise assumed to be white Gaussian.

Using the feedback configuration of the Kalman filter we can write the following equations:

$$\underline{x}(t) = \underline{F} \ \underline{\hat{x}}(t) + \underline{G} \ \underline{w}(t) + \underline{K}[\underline{z} - \underline{H} \ \underline{\hat{x}}(t)]$$
(35)

and

$$\dot{P}(t) = \underline{F} \underline{P} + \underline{P} \underline{F}^{T} + \underline{G} \underline{Q} \underline{G}^{T} - \underline{P} \underline{H}^{T} \underline{R}^{-1} \underline{H} \underline{P}$$
(36)

where

- $\underline{P}(t)$ = the covariance matrix
- <u>K</u> = <u>P</u> <u>H</u>^T <u>R</u>⁻¹ the Kalman filter gains matrix

 \underline{R} = the measurement noise covariance matrix

In order to achieve numerical results via computer simulation we write the predicted error states of our system in explicit form as below with the help of Table IV in which the system states and their corresponding symbols are defined:

$$\dot{x}(1) = -\dot{\lambda}(\sin L)\hat{x}(2) - \dot{\lambda}(\sin L)\hat{x}(4) + (\cos L)\hat{x}(7) + AA + + K_{11}[\hat{x}(8) - \hat{x}(4)] + K_{12}[\hat{x}(9) - \hat{x}(5)] \quad (35-a)$$

$$\dot{\hat{x}}(2) = \dot{\lambda}(\sin L)\hat{x}(1) + \dot{\lambda}(\cos L)\hat{x}(3) - \hat{x}(6) + BB + + K_{21}[\hat{x}(8) - \hat{x}(4)] + K_{22}[\hat{x}(9) - \hat{x}(5)] \quad (35-b)$$

$$\dot{\hat{x}}(3) = -\dot{\lambda}(\cos L)\hat{x}(2) - \dot{\lambda}(\cos L)\hat{x}(4) - (\sin L)\hat{x}(7) + SS + + K_{31}[\hat{x}(8) - \hat{x}(4)] + K_{32}[\hat{x}(9) - \hat{x}(5)] \quad (35-c)$$

$$\dot{\hat{x}}(4) = \hat{x}(6) + K_{41}[\hat{x}(8) - \hat{x}(4)] + K_{42}[\hat{x}(9) - \hat{x}(5)] \quad (35-d)$$

(35-g)

Assuming the input forcing vector as white Gaussian noise whose strength is related to the value of the variance of each input error source (the corresponding one) computer simulation was proceeded in the following way.

First with the help of the RICATI FILTER computer program available at the NPS W.R. Church Computer Center we solved the corresponding for our study Ricati equation of covariance propagation obtaining the Kalman filter gain matrix. The data we used to run the above program are provided in Tables III and V. A listing of the data formulation for the RICATI FILTER program is given in Appendix D.

The calculated from the above program values of the Kalman filter gains for a processing period of four hours are given in the following Table VI.

Additional runs of the above program have been contacted for processing periods up to 36 hours and it has been observed that the Kalman filter gains reach a steady state

condition for which their values are not very much different from those achieved for a 4 hour processing period.

So in the following calculations and computer simulation we have used the values of the Kalman filter gains resulted for a 4 hour simulation period.

Having available the values of Kalman filter gain matrix elements which are used to multiply the residuals in the appropriate equations in order to achieve the predicted error states of the integrated I.N.S./G.P.S. system, the appropriate program has been formulated in order to solve the error differential equations (32) described above, with the use of the available routine INTEG2S slightly modified for accurate evaluation and plot of the error state variables.

The simulation results for the I.N.S./G.P.S. system operation for a period of four (4) hours are presented below in Figures 64 through 93. We can easily observe that all the state error variables of the combined I.N.S./G.P.S. system are damped out and the resulting value of the errors after a period of one (1) hour is small enough so that the operation of our system model can be characterized as successful.

Specifically in Figure 64 we observe that the north level error of our system is dropped down to 0.025 milliradians after one (1) hour even if the starting initial

condition value was 0.14 milliradians. Furthermore at the end of a 4 hour period the error has been diminished to the value of 0.005 milliradians which is subject to error reduction by a factor of 28.

In Figures 65 and 66 the East and Azimuth attitude errors are presented respectively where similar as with the north attitude error observations occur.

The Y position error behavior is presented in Figure 67. There we can see that even if we started from an initial condition error of 0.17 milliradians (or 3256 ft) after one hour processing the error has been diminished to only 0.028 milliradians (or 536 ft) and furthermore after a four hour period this error drops down to 0.01 milliradians (or 191.5 ft).

The X position error damping out seems to be more attractive since from Figure 68 we can see that after one hour the error drops down to 0.020 milliradians (or 383 ft) and at the end of a four hour period the error is diminished to 0.0002 milliradians (or 3.83 ft) which is very small considering also that we started with an initial condition value of the X position error of 0.17 milliradians (or 3256 ft).

Figure 69 presents the propagation of Y velocity error. It is easily observed that this error drops down to the very small value of 0.040 milliradians/hour (or 68 x 10^{-4} ft/sec)

after one hour and to the negligible error of 0.002 milliradians/hour (or 34×10^{-5} ft/sec) which provides the advantage of very accurate evaluation and tracking of the Y velocity state variable.

Similar with the above considerations and even better results occur for the case of the X velocity error of the integrated I.N.S./G.P.S. system. We see from Figure 70 that this error starting from an initial condition value of 0.34 milliradians/hour (or 2 ft/sec) drops down to 0.1 milli-radians/hour (or 17 x 10^{-3} ft/sec) after one hour operation and furthermore down to 0.002 milliradians/hour (or 34 x 10^{-5} ft/sec) after a period of four hours which again denotes a very accurate tracking of the X velocity error state variable.

In Figures 71 and 72 the normalized inserted and measurement noise of the combined I.N.S./G.P.S. systems are presented respectively.

Thinking of the operation of our system in the long term, results of the computer simulation are presented in Figures 73 through 79. Using the same input data for our I.N.S./G.P.S. system model and running the program for a 36 hour process we see that the behavior of the feedback configration of the Kalman filter in our system continues to be attractive throughout the long term period of interest without diverging at any moment.

In addition to the above considerations, in order to make our system more realistic and compatible to the real world's conditions we put some noise in the two error state equations of X and Y position which did not include any noise from our theoretical design of the system. So we replace the two equations (35-d) and (35-e) in our system of equations with the following two equations:

 $\hat{x}(4) = \hat{x}(6) + AA + K_{41}[\hat{x}(8) - \hat{x}(4)] + K_{42}[x(9) - \hat{x}(5)] (35-d')$ and

 $\hat{x}(5) = \hat{x}(7) + AA + K_{51}[\hat{x}(8) - \hat{x}(4)] + K_{52}[\hat{x}(9) - \hat{x}(5)] (35-e^{1})$

Assigning to the strength of this intentionally inserted noise a value similar to that of the strength of the gyro drift (that is a value of $0.0685 \times 10^{-6} \text{ [rad]}^2$) we ran the same program and we achieved results proving that the combined I.N.S./G.P.S. system reacted in a way exactly the same as it had reacted without the inserted noise in the X and Y position error equations. So we make the conclusion that the intentionally inserted noise did not affect the operation of our system model neither from the accuracy point of view nor from the time point of view.

The above considerations and results can be seen in Figures 80 through 86 for the four (4) hours short term process and in Figures 87 through 93 for the 36 hours long term operation.

In Table VII on the next page we summarized the state errors of the combined I.N.S./G.P.S. system after a period of two and four hours operation. In the same table we included the starting initial condition for each error state in order to make our comparisons easier and handy. The results included in Table VII are those achieved from the computer simulation without any noise corrupting the two error states of Y and X position. But since the addition of noise with strength similar to that of the gyro drift $(0.0685 \times 10^{-6} [rad]^2)$ dr not affect the system model operation as mentioned before, the same Table VII represents also the summary of state errors for the real world's system model of the I.N.S./G.P.S. system.

Up to now we considered our system to be corrupted by white Gaussian input noise. Since in the real world in many cases the presence of colored noise is apparent we must consider the operation of our I.N.S./G.P.S. system under the presence of such noise and compare the results with those achieved when the system was driven by white noise.

In the following section a realistic modeling of the I.N.S. component errors is discussed and the results of the computer simulation are presented together with the comparison conclusions of the system's operation under colored noise versus white noise corruption.

C. I.N.S. COMPONENT ERROR MODELS

In Chapter III equation (31) indicates that the I.N.S. component errors consist of three gyro drift uncertainties, two accelerometer measurement uncertainties, two gyro torquer scale factor errors and two geodetic uncertainties. Realistic modeling of the two major error components, the gyro drift and the accelerometer measurement is described below.

1. Gyro Drift Uncertainties

The three gyro drift uncertainties, $(u)_{w_{N}}$, $(u)_{w_{E}}$, $(u)_{w_{D}}$ are each modeled as an exponentially-correlated (colored) noise plus an additive random (white) noise:

 $(u)_{\omega_{i}} = \delta_{i} + W_{g_{i}}$; i = N, E, D (37) where the colored noise is determined by:

$$\dot{\delta}_{i} = -\frac{1}{t_{g_{i}}} \delta_{i} + v_{g_{i}}$$
(38)

The t represents the correlation time of the colored noise and the v the strength of the driving white noise obtained using the specified variance $\sigma_{\delta i}^2$ of the colored noise and the formula

$$Q_{v_{g_{i}}} = 2\sigma_{\delta i}^{2/t} g_{i}$$
(39)

The quantity w_{g_i} is a white noise of specified strength.

2. Accelerometer Measurement Uncertainties

The accelerometer measurement uncertainties $(u)f_N$ and $(u)f_E$ are modeled in the same way as the gyro drift uncertainties, as colored noise plus white noise:

$$(u)f_{i} = a_{i} + w_{a_{i}}; \quad i = N, E$$
 (40)

where again w_a is the white noise of specified strength and the colored noise is given by:

$$\dot{a}_{i} = -\frac{1}{t_{a_{i}}} a_{i} + v_{a_{i}}$$
 (41)

where t is the correlation time of the colored noise with variance $s_{a_i}^2$, and the strength of the driving white noise v_{a_i} is given by:

$$Q_{v_{a_{i}}} = 2 \sigma_{a_{i}}^{2/t_{a_{i}}}$$

$$(42)$$

3. Computer Simulation Results

Using the same set of equations (35-a) through (35-g) but introducing the appropriate state augmentation in order to incorporate the exponentially correlated noise for the gyro drift and the accelerometer measurement, we simulated the operation of the combined I.N.S./G.P.S. system and achieved the following result.

The operation of the system proved to be excellent for all the used correlation times from 60 seconds up to 3600 seconds (1 hour). The attitude and navigation errors were found to behave in the same way being minimized after a period of one hour. Furthermore, the variation of the attitude and navigation errors is similar with the case of the white noise driven I.N.S./G.P.S. combined system which again is similar, if not exactly the same, with the ideal I.N.S./G.P.S. system.

In Figures 94 through 100 we present the I.N.S./G.P.S. system operation for an exponentially correlated input noise with a correlation time of 1 hour (3600 sec). We can easily see in these figures that the behavior of the combined I.N.S./G.P.S. system is the same with that when white noise drives the input except for a very small and negligible increase of the attitude and navigation errors after the first hour of operation.

V. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

From knowledge gained throughout this work and based on the material presented in our study, the following conclusions are drawn:

As far as the I.N.S. errors are concerned we saw that

1. The effects of constant gyro drift errors for the stationary case are related to Foucault modulation which has only a second-order effect on the longitude and latitude error states and permit us to neglect it in cheap systems designed for navigational purposes.

2. For the case of easterly flight, latitude errors were reduced by a factor of 1.557 which correponds to the ratio $\frac{1}{\omega_{ie}}$ and Foucault modulation period reduced analogously from 33.9 hours to 21.8 hours.

3. For the westerly flight, case longitude and latitude errors grow in approximate proportion to the time-drift rate product.

4. The accelerometer bias errors have the same effects for the stationary case as the gyro drift errors.

5. The Foucault modulation period increased by the same as above factor of 1.557 for the easterly flight case, while for the westerly flight decreased by a factor of 0.442

corresponding again to the ration $1/\omega_{ie}$ for the specific case.

6. The error sensitivities remain unchanged for the easterly and westerly flight and again we may neglect Foucault modulation as producing only second-order effects on the navigation states.

For the combined I.N.S./G.P.S. system the results achieved by this study proved that the errors of the system's state variables are damped out in less than one hour, denoting effective and successful operation of the G.P.S. aiding to the I.N.S. Specifically:

7. Using suboptimal Kalman filter gains for one hour process, the Y-position error reduced from its initial value by a factor of 6 in one hour and by a factor of 17 in four hours.

8. With the same suboptimal Kalman filter gains of one hour process, the X-position error proved the system more attractive since the error reduced by a factor of 8.5 after one hour and by a factor of 856 after four hours.

9. Both the X and Y-velocity errors damped out very quickly so that after one hour the Y-velocity error reduced by a factor of 312.5 and the X-velocity error by a factor of 117.6, while for a four-hour process both velocity errors reduced by a factor of 571 from its initial value.

10. The consideration of long term filter's operation proved no divergence at all for a process of 36 whole hours. The errors remained at the same attractive levels as for the four-hour process, fact which enables us to conclude that the combined I.N.S./G.P.S. system works with excellent results for both short and long term periods.

11. Finally the operation of the combined I.N.S./G.P.S. system under exponentially correlated input noise proved to be excellent for all different correlation times from 60 sec up to 3600 sec, with a negligible increase in the attitude and navigation error magnitudes after the first hour of operation.

B. RECOMMENDATIONS

Continued study of this work can be based on the following recommendations:

1. A Kalman filter design study where the primary emphasis will be placed upon determination of the "best" filter state variable vector. A general covariance analysis program for the analysis, evaluation and design of Kalman filters, which will help this study, has been tape recorded from the Wright Patterson Air Force Base, Air Force Avionics Laboratory and modified by the author for use in N.P.S. campus computer.

2. Investigation of various measurement rates using the external range measurements from a set of satellites in view

among the 18 of the G.P.S. and Kalman filter's performance for these rates.

3. Possible use of a flight profile generator program, which will generate simulated flight patterns instead of considering specific only cases for stationary, easterly, and westerly flights, together with a satellite motion generator required to provide necessary information regarding the satellites' orbital elements. This recommendation applies only to U.S. citizens since such programs already exist but they are classified.

4. Investigation and results evaluation for the effects upon filter performance when range-rate measurements are available. Then a comparison with the usage of only range measurements could be extracted. Another aspect for investigation could be the satellite bearing measurements to declare best observable satellites and to provide better accuracy.

5. Finally a comparison of sequential versus simultaneous measurement would be another area of interest. The performance of a filter working with sequential measurements is of interest primarily, because of the increased cost of equipment equired to perform simultaneous measurements and computations as compared to the sequential ones.

APPENDIX A

A SIMPLE EXAMPLE: KALMAN FILTER APPLICATION TO A RADAR POSITION AIDED INERTIAL NAVIGATION SYSTEM

I. INTRODUCTION

The application of a Kalman filter to a simplified radar position aided inertial navigation system was investigated as a first step of our study. Since the case appears to be easy to understand difficult concepts and the results prove the design expectations we present hereafter this simple case formulated according to the concepts and the outline of Ref. 2.

The I.N.S. system was modeled as white noise driving a $1/s^2$ plant. Radar measurements were assumed to be available and were similarly corrupted by white noise.

The differential equations describing the system and the Kalman filter were numerically integrated to yield the response for a wide range of input conditions and system noise statistics. Particular attention was paid to conditions in which the noise statistics employed in the filter were different from the statistics of the noise actually driving the system dynamics and measurements.

For all cases considered, including those for which intentional mismatches in the noise statistics were

introduced, the filter was found to perform in an entirely satisfactory manner. This is the filter reliably and quite accurately tracked the system's dynamics even at the presence of at times rather severe levels of noise.

In the section to follow, the theoretical development of the Kalman filter equations will be presented. This development is based on that given in Chapter 6 of Maybeck [Ref.2] and according to explanations given in class notes from Prof. Collins [Ref. 12].

Next, a discussion of simulation results will be given, in which the various cases considered are outlined, and the performance of the filter in each case is described. Finally an overall summary and conclusions regarding the observed performance of the filter over a wide range of test conditions, is presented.

II. I.N.S. AIDED BY POSITION DATA

For this problem, the model of the I.N.S. is simply a double integration of noise-corrupted acceleration information, as depicted in Fig. 101. The noise w is a white Gaussian noise of zero mean and variance Kernel

$E[w(t)w(t+\tau)] = Q\delta(\tau)$

entering at the acceleration level, and it is meant to model the errors corrupting the I.N.S. accelerometer outputs (accelerometer biases and noise, platform misalignment,

Figure 101. I.N.S. Aided by Position Data.

etc.). The noise-corrupted acceleration is integrated once to yield I.N.S.-indicated velocity (v_i) , and a second time to obtain inertially-indicated position (r_i) .

Similarly a simple model for the radar or radio navigation aid is the true position (r_t) corrupted by noise u, which is again white Gaussian with zero mean.

The two error state variables for this case are:

$$sr(t) = r_{i}(t) - r_{t}(t)$$
 (A-1)
 $\delta v(t) = v_{i}(t) - v_{t}(t)$

The measurement to be presented to the filter is the difference between the inertially indicated position and that measured by the radar or radio navigation aid.

From Figure 96 we have:

$$z(t) = r_{i}(t) - r_{r}(t)$$

= [r_{t}(t) + \delta r(t)] - [r_{t}(t) - u(t)] = (A-2)
= \delta r(t) + u(t)

This is a measurement of the error $\delta r(t)$ corrupted by noise u(t).

To establish the state dynamics model for the error states, first let us consider the total states r_i and v_i .

$$\begin{bmatrix} \dot{\mathbf{r}}_{\mathbf{i}} \\ \dot{\mathbf{v}}_{\mathbf{i}} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \mathbf{r}_{\mathbf{i}} \\ \mathbf{v}_{\mathbf{i}} \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \begin{bmatrix} \mathbf{a}_{\mathbf{t}} + \mathbf{w} \end{bmatrix}$$
(A-3)

The true position velocity and acceleration are related by:

$$\begin{bmatrix} \mathbf{\dot{r}}_{t} \\ \mathbf{\dot{v}}_{t} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \mathbf{r}_{t} \\ \mathbf{v}_{t} \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \mathbf{a}_{t}$$
(A-4)

Subtracting (A-4) from (A-3) and using the error state definitions of (A-1) we find the desired relation as:

$$\begin{bmatrix} \delta \mathbf{r} \\ s \mathbf{v} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \delta \mathbf{r} \\ \delta \mathbf{v} \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \mathbf{w}$$
(A-5)

The measurement model z can be expressed in terms of errors as:

$$z(t) = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{bmatrix} \delta r \\ \delta v \end{bmatrix} + u(t) = \underline{H} \underline{x} + u(t)$$

Since we would like to design a Kalman filter for this situation we need to solve the RICATI equation as below:

$$\dot{P} = FP + PF^{T} + GQG^{T} - PH^{T}R^{-1}HP$$
 (A-6)

where

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \text{ and } P_{12} = P_{21}$$

Figure 102. Kalman Filter Block Diagram

186

. . .

--.

$$E[w(t)w(t+\tau)] = Q\delta(\tau)$$
$$E[u(t)u(t+\tau)] = R\delta(\tau)$$

Solving for RICATI equation for our case we get:

$$\begin{bmatrix} \dot{P}_{11} & \dot{P}_{12} \\ \dot{P}_{21} & \dot{P}_{22} \end{bmatrix} = \begin{bmatrix} 2P_{12} - (P_{11})^2/R , P_{22} - P_{11}P_{12}/R \\ P_{22} - P_{11}P_{12}/R , Q - (P_{12})^2/R \end{bmatrix}$$
(A-6a)

For the steady state case where $\dot{P} = 0$ we get the elements of covariance matrix in terms of Q, R and the ratio $(Q/R)^{1/4}$ which represents the natural frequency of the system:

$$P_{11} = 2 Q^{1/4} R^{3/4}$$

$$P_{12} = Q^{1/2} R^{1/2} = P_{21} \qquad (A-7)$$

$$P_{22} = 2 Q^{3/4} R^{1/4}$$
The Kalman filter equation is
$$\hat{x} = F\hat{x} + G\underline{u} + K(t) [z - H\hat{x}] \qquad (A-8)$$

which in terms of error quantities becomes:

$$\begin{bmatrix} \hat{s}\hat{r} \\ \hat{s}\hat{v} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \hat{s}\hat{r} \\ \hat{s}\hat{v} \end{bmatrix} + K \begin{bmatrix} z - \hat{s}\hat{r} \end{bmatrix}$$
(A-9)

where $K = PH^TR^{-1} =$

$$= \begin{bmatrix} P_{11} & P_{12} \\ R_{21} & R_{22} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \begin{bmatrix} 1 \\ R \end{bmatrix}$$
$$= \begin{bmatrix} 1 \\ 1 \\ 1 \\ 21 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$
(A-10)

and using the results of the RICATI equation solution we can write

$$K = \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} = \begin{bmatrix} 2 & \omega_n \\ (\omega_n)^2 \end{bmatrix} \quad \text{where } \omega_n = (\frac{Q}{R})^{1/4} \text{ [rad/sec]} \quad (A-11)$$

From the above information we can draw the block diagram of the Kalman filter for this system as shown in Figure 102.

The initial transient behavior of the filter gains K_1 and K_2 depends on P_0 , but they are within a few percent of their steady state values (independent of P_0) after $w_n t = 2$, so a prediction of time to reach steady state would be approximately $2/w_n$ seconds [Ref. 2].

The filter can be put into either feedforward configuration or feedback configuration. Since for our study we use the feedback configuration we present here the outline and the results for this configuration. A block diagram of the system is presented in Figure 103 as depicted in Maybeck's work [Ref. 2]. This block diagram allows us to write the

system's equations which we will simulate numerically to achieve the system's performance.

We define the outputs of the I.N.S. system corrected by feedback from the filter as follows:

$$\hat{\mathbf{r}}(t) = \mathbf{r}_{1}(t) - \hat{\delta \mathbf{r}}(t) \qquad (A-12)$$

$$\hat{\mathbf{v}}(t) = \mathbf{v}_{1}(t) - \hat{\delta \mathbf{v}}(t)$$

which will be a very helpful mathematical tool since the most straightforward means of generating feedback implementations is to write the system and filter equations in terms of corrected system states. (For our case corrected I.N.S. states.)

Then using the equations (A=3) and (A=9) together with equation (A=8) we can write the matrix form of the system equations as:

$$\begin{bmatrix} \dot{r}_{t}(t) - \delta \dot{r}(t) \\ \dot{v}_{1}(t) - \delta \dot{v}(t) \\ \dot{v}_{1}(t) - \delta \dot{v}(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} r_{1}(t) - \delta \dot{r}(t) \\ v_{1}(t) - \delta \dot{v}(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \begin{bmatrix} a_{t}(t) + w(t) \end{bmatrix} \begin{bmatrix} K_{1}(t) \\ K_{2}(t) \end{bmatrix} \begin{bmatrix} z(t) - \delta \dot{r}(t) \end{bmatrix}$$
and finally we get the simple form:
$$\begin{bmatrix} \dot{\hat{r}}(t) \\ \dot{\hat{v}}(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \hat{r}(t) \\ \hat{v}(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \begin{bmatrix} a_{t}(t) + w(t) \end{bmatrix} + \begin{bmatrix} K_{1}(t) \\ K_{2}(t) \end{bmatrix} \begin{bmatrix} r_{r}(t) - \hat{r}(t) \end{bmatrix}$$
(A-13)
(A-13)
(A-14)

In the next section the programming and simulation results of the system is presented.

III. COMPUTER SIMULATION AND RESULTS

We simulated the system for different input signals, different noise characteristics (zero mean Gaussian noise with different variances) to see the effect of the filter for error estimation.

From the block diagram of the system in Figure 103 we can write the following set of equations which we will use to get results by numerical computer simulation.

$$\dot{x}(1) = \dot{r}_{t} = v_{t}$$

$$\dot{x}(2) = \dot{v}_{t} = a_{t}$$

$$\dot{x}(3) = \dot{r}_{1} = v_{1}$$

$$\dot{x}(4) = \dot{v}_{1} = a_{t} + w$$

$$\dot{x}(5) = \dot{P}_{11} = 2P_{12} - (P_{11})^{2}/R$$

$$\dot{x}(6) = \dot{P}_{12} = P_{22} - P_{11}P_{22}/R$$

$$\dot{x}(7) = \dot{P}_{22} = Q - (P_{12})^{2}/R$$

$$\dot{x}(8) = \delta \dot{r} = \delta \dot{v} + K_{1}(z - \delta \hat{r})$$

$$\dot{x}(9) = \delta \dot{v} = K_{2}(z - \delta \hat{r})$$

$$x(15) = r_{r} = r_{t} - u$$

$$x(16) = \hat{v} = v_{1} - \delta \dot{v}$$

)___

 $x(17) = \hat{r} = r_i - \delta \hat{r}$ $x(32) = K_2 = P12/R$ $x(19) = K_1 = P_{11}/R$ $x(20) = z = r_i - r_t + u$ x(21) = w

x(22) = u

The above set of differential equations of the I.N.S. system and feedback Kalman filter were numerically integrated using INTEG2 computer routine in conjunction with a routine (LNORM) for generating Gaussian distributed random numbers to represent the noise into the system. Typical simulation runs used an integration step size of 0.01 seconds and a total run time of 36 seconds by which point the filter had easily achieved steady-state operation in most cases.

Shown on the next page is a run summary representing the various conditions that were tested. For each of six cases, the covariances of the measurement noise (R) and process noise (Q) are indicated. Note that in a number of cases, the noise statistics used in the filter were chosen to be different from those characterizing the input noise entered into the system. This intentional "mismatch" was done to

investigate filter performance under conditions where the true "real world" noise statistics are inadequately or poorly known.

In particular it was desired to determine whether any instances of filter "divergence" could be observed as a result of the mismatch in system noise statistics. It is noteworthy that for all conditions tested, the filter performed in an entirely satisfactory manner with no evidence of divergence.

It should be noted here that in Table XI the noise covariances Q and R actually represent the statistics of <u>Discrete Noise</u> entering the system at the integration interval $\Delta t = 0.01$ seconds. That is:

> $Q = E[w_k w_k^T]$ where $t_k = k\Delta t$ $R = E[u_k u_k^T]$

As it is pointed out by Bryson and Ho [Ref. 13] the numerical integration is a discrete approximation to a continuous system whose noise processes have spectral densities given by

 $E[w(t)w(\tau+t)] = Q'\delta(\tau)$ $E[u(t)u(\tau+t)] = R'\delta(\tau)$

The relation between Q and Q' and R and R' is according to Bryson:

 $Q' = Q \cdot \Delta t$ $R' = R \cdot \Delta t$

Also shown in Table XI for each case, are the filter natural frequency and the steady-state values of the Kalman gains.

A brief discussion will now be given of the results for each of the six cases. Detailed plots of the variables of interest for each case are attached and will be referred to in the subsequent discussion.

1. Case I

For this case we used R = 10,000 and Q = 1 for the filter. The actual noise however is mismatched with $R_t = 100$ and $Q_t = 1$ and thus the filter assumes the measurement noise of the radar position data considerably higher than the case is actually. Shown in the attached plots on Figures 104 and 105 is the type of noise actually entered into the system using a Gaussian random number generator. Also shown are the histories of the Kalman filter gains K_1 and K_2 versus time. The performance of the filter for this case is outstanding as evidenced by the two plots for Case I in Figures 108 and 109. Here the estimated position out of the filter coinsides with the true position

denoting that the filter tracks the system extremely well. Among the other attached plots, Figure 112 presents the noise corrupted radar position in a very imposing way.

2. Case II

This case represents one in which the filter and external noise are "tuned" so that the same noise statistics are employed with R = 100 and Q = 25. Again the Kalman gains are plotted indicating the time of steady-state condition in Figure 114 and 115. As it is depicted from Figures 116, 117 and 118 the Kalman filter rapidly "locks-on" to the true position and velocity and accurately tracks the system thereafter.

3. Case III

In this case the filter and external noise are "tuned" with R = 100 and Q = 1. The system's initial conditions now include a 10 ft/sec² constant acceleration and it was desired to see how well the Kalman filter kept up with the changing input. Once again the performance of the filter in accurately tracking the system is excellent. This can be verified looking at Figures 124 and 125 and 126 and 127 respectively where we can see the coinsidence of the true and estimated position and velocity.

4. Case IV

For this run the filter and external noise are again "tuned" but with increased statistics of R = 400 and Q = 50.

The attached set of plots in figures 131 through 138 present the system and the filter operation proving the accurate and satisfactory tracking of the system

5. Case V

Now the filter perceives the radar measurement noise to be higher than it actually is. The statistics used for this case were R = 400 and Q = 50 for the filter while for the external noise we used $R_t = 50$ and $Q_t = 50$. The reliability and the accuracy of the system is again depicted in the attached plots for Case V in Figures 139 through 146.

6. Case VI

In the last case considered the statistics of the random process noise exciting the I.N.S. accelerometers was mismatched with that assumed in the filter. Here we used $Q_t = 50$ and Q = 10. The radar measurement noise $R_t = A = 400$ was assumed the same. The set of plots in Figures 147 through 154 indicate very good performance of the filter despite the intentional mismatch introduced for the system driving noise.

IV. CONCLUSIONS

Following the development of Reference 2, simplified equations characterizing the Kalman filter were derived and numerically integrated to yield the filter response to a wide range of input conditions and system noise statistics. Particular attention was paid to conditions in which the

noise statistics employed in the filter differed from the statistics of the noise records actually driving the system dynamics and measurements.

For all cases considered including those for which intentional mismatches in the noise statistics were introduced, the filter was found to perform in an entirely satisfactory and reliable manner. By that is meant that the filter very accurately tracked the system dynamics even in the presence of at times rather sever levels of noise.

Examination of typical time histories for the variables of interest, showed that the filter Kalman gains K_1 and K_2 rapidly settled to their theoretical steady state values within a time short compared to the average run time. This was accompanied by the filter range and velocity estimates rapidly locking on to the true system position and velocity and accurately tracking it thereafter.

It is concluded then that the Kalman filter configuration discussed here above performed extremely well over the range of conditions considered.

APPENDIX B

SATELLITE GEOMETRY, VIEW AND RANGE ERRORS

The range measurement equation will first be developed. Next a simple program has been formulated to verify the "observability" and "suitability" of at least four satellites at any given time.

A. RANGE MEASUREMENT EQUATION

The range measuring process is characterized by a set of equations, called the range divergence equations, which are generated by the user from a combination of I.N.S. and satellite information. This range measurement process involves the comparison of a measured value of range against a predicted value of range.

The measured range to a satellite is determined by measuring the incremental phase shift between the satellite's clock and that of the control station which supports the user. These clocks were synchronized at an earlier time. The computed range on the other hand is obtained from satellite ephemeris data and user I.N.S. supplied position information.

The fact is that both the measured and the computed range values contain in general errors; so by subtracting the computed range value from the measured one, the

different will contain only the associated errors. This difference is called "the range divergence." A Kalman filter can be constructed to estimate the errors and improve the accuracy of the raw range data if these errors can be modeled as the outputs of linear systems driven by white Gaussian noise [Ref. 8].

1. Range Divergence

The case of a single satellite will be considered, in order to avoid the notational inconvenience of using superscripts or subscripts to keep track of which satellite is being referred to. The results are identical for any one of the 18 satellites and therefore very easily extended.

 \underline{r} = User-Satellite position vector \underline{r}_a = Earth-User position vector \underline{r}_s = Earth-Satellite position vector

Figure 155. Range Vector Definition

The range vector of interest is the vector \underline{r} from the user to the satellite. It is explicitly related to the two vectors \underline{r}_a and \underline{r}_s which are defined and illustrated in the above figure. From the geometry it follows that

$$\underline{r} = \underline{r}_{s} - \underline{r}_{a} \tag{B-1}$$

where

$$\mathbf{r} = |\underline{\mathbf{r}}| = |\underline{\mathbf{r}}_{s} - \underline{\mathbf{r}}_{a}| = \underline{\mathbf{r}} \cdot \underline{\mathbf{r}} = (\underline{\mathbf{r}}_{s} - \underline{\mathbf{r}}_{a}) \cdot (\underline{\mathbf{r}}_{s} - \underline{\mathbf{r}}_{a}) \quad (B-2)$$

The measured range to the satellite, r', is composed of two parts

$$\mathbf{r'} = \mathbf{r} + \delta \mathbf{r'} \tag{B-3}$$

where, r is the true range and $\delta r'$ is the error in the measured range to the satellite. The computed range to the satellite, r", is in a similar way written:

$$\mathbf{r}'' = \mathbf{r} + \delta \mathbf{r}'' \tag{B-4}$$

where, r is again the true range and δr " is the error in the value of the computed range.

The quantity then, that is being observed, is the difference of these two range values and it is the called "range divergence," Ar.

$$\Delta r = r' - r'' = \delta r' - \delta r''$$
 (B-5)

2. Errors in Measured Range

To model the range measurement error, a knowledge of the various error sources which are contained in the measurement is required and fitting these error sources with empirical data. The model used in our study is a simplified version of the one found in [Ref. 4] with additional information of [Ref. 5]. It is a linear combination of three components for each satellite measurement corrupted by white Gaussian noise (w). Each of the separate components is a linear system which is driven by white Gaussian noise.

The range measurement error is modeled by:

$$\delta \mathbf{r}' = \delta \mathbf{b} + \mathbf{c}(\delta \mathbf{T}_{,1} - \delta \mathbf{T}_{,2}) + \mathbf{w}$$
 (B-6)

where

δb = range bias
c = the speed of the light
δT_u = user clock phase error
δT_s = satellite clock phase error

w = measurement noise

The error in the range measurement due to ionosphere delay is assumed to be included in the satellite clock phase/range error. This is a function of the elevation angle and on the

order of 15 feet as a good approximation. The bias term, sb, in the above equation accounts for the minor effect of both speed of light bias and tropospheric delay uncertainties in each one of the four satellite range measurements.

3. Errors in Computed Range

The computed satellite position includes error which depends on the ephemeris data errors, while the I.N.S. errors account for the uncertainty in the user's position. So far we have

$$\frac{\mathbf{r}_{s}}{\mathbf{s}} = \frac{\mathbf{r}_{s}}{\mathbf{s}} + \frac{\delta \mathbf{r}_{s}}{\mathbf{s}}$$
(B-7)

$$\mathbf{r}_{a}" = \mathbf{r}_{a} + \delta \mathbf{r}_{a}" \tag{3-8}$$

The error equation is obtained now since,

 $(r'')^2 = r'' \cdot r''$

and by taking the differential of both sides we get

 $2r^{n}\delta r^{n} = r^{n} \cdot \delta r^{n} + \delta r^{n} \cdot r^{n}$

or

$$\delta r'' = \frac{1}{r''} (\underline{r''} \cdot \delta \underline{r''}) = (\frac{1}{r''} \underline{r''}) \cdot \delta \underline{r''}$$
 (B-9)

We can easily notice that the quantity, $\frac{1}{r^{\prime\prime\prime}} \underline{r}^{\prime\prime\prime}$, of the right hand side is a unit vector from the user to the satellite.

$$\underline{i}_{r''} = \frac{1}{r''} \underline{r}'' ; \ \underline{i}_{r''} = [i_{r_N}, i_{r_E}, i_{r_D}]^T \qquad (B-10)$$

and also that

$$\delta \underline{r}^{"} = \delta \underline{r}_{8}^{"} - \delta \underline{r}_{a}^{"} \qquad (B-11)$$

Finally the computed error is written as

$$\delta r'' = \underline{i}_{r''} \cdot (\delta \underline{r}_{s}'' - \delta \underline{r}_{a}'') \qquad (B-12)$$

Without any significant accuracy loss, it is assumed that the earth-satellite range error, $\delta_{\underline{r}_{S}}$ is approximately zero for the following logic sequence. Satellite orbital parameters are updated by the ground tracking network on a periodic basis and relayed to the user along with the range data. This ephemeris data is quite accurate and any uncertainties in computed satellite range can be accounted for by increasing the satellite clock phase error [Ref. 4].

Thus the computed range error can be written

$$\delta r'' = -\frac{i}{r''} \cdot \frac{\delta r}{\delta r}$$
(B-13)

The computation of the above equation requires values for the unit vector from the user to the satellite and also current values for the north, east and azimuth I.N.S. position error states

$$\delta r_a = [\Delta N, \Delta E, \Delta D]^T$$

Since we are dealing with a stochastic process simulation the root-mean-squared (RMS) values of the covariance of the three position errors are used.

The final form of the range divergence equation is obtained now by substitution of equations (B-6) and (B-13)into the general form equation (B-5)

 $\Delta r = \underline{i}_{r''} \cdot \underline{\delta r}_{a''} + c \delta T_{u} - c \delta T_{s} + \delta b + w \qquad (3-14)$

Since at least four satellites are required as observables to correct for the three components of position and the clock phase (or time difference), a minimum of four range divergence equations need to be solved simultaneously.

B. SATELLITE OBSERVABILITY

In the following development of equations we will drop out the double prime (") for notational convenience. A given satellite must be in-view by the user in order to obtain certain measurements. It is then required that the satellite must be above some specified minimum angle of the user's horizon to get a useful signal. This minimum angle depends upon the capabilities of the user-equipment and can be characterized as arbitrary. In our study the nominal value of this angle was selected of ten degrees. This observability criterion together with the suitable selection of 18 satellites as the total number of satellites for global coverage, insures that regardless of the user's

position, a sufficient and reasonable number of satellites will always be in-view, from which a "best set" of the required four satellites may be chosen.

In the following a method for determining whether or not a satellite is observable is presented.

Figure 156. Observability-Criterion Geometry

From the above figure and for the following calculations:

 E_{min} = minimum angle of elevation for useful signal D_{max} = 90° - E_{min} <u>r</u> = User-Satellite position vector <u>r</u> = Earth-Satellite position vector \underline{r}_a = Earth-User position vector

 C_e^n = earth to navigation transformation matrix

The quantity \underline{r}_a is most readily expressed in the navigation frame as

$$\underline{\mathbf{r}}_{\mathbf{a}}^{\mathbf{n}} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{R}_{\mathbf{h}} \mathbf{h} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{R}_{\mathbf{h}} \end{bmatrix}$$
(3-15)

where

R = radius of Earth

h = altitude of user

and the superscript, n, denotes the frame in which the vector is coordinated (navigation frame).

Since the earth-satellite position vector in the earth frame, \underline{r}_s^e , is derived from the ground track latitude and longitude of the satellite in the orbit generator and is readily available, the vector \underline{r} from the user to the satellite lite coordinatized in the navigation frame is written as

$$\underline{\mathbf{r}}_{\mathbf{n}} = \underline{\mathbf{r}}_{\mathbf{s}}^{\mathbf{n}} - \underline{\mathbf{r}}_{\mathbf{a}}^{\mathbf{n}} = \mathbf{C}_{\mathbf{e}}^{\mathbf{n}} \mathbf{r}_{\mathbf{s}}^{\mathbf{e}} - \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{R} \end{bmatrix}$$
(B-16)

The unit vector along \underline{r}^n is given by

$$\underline{i}_{r} = \frac{1}{r} \underline{r}^{n} ; r = \underline{r}^{n} \cdot \underline{r}^{n} \qquad (B-17)$$

From the geometry we observe that the azimuth component of this unit vector is evaluated as the sine of the elevation angle, E, or the cosine of its complementary angle A. That is

$$\underline{i}_{r} \cdot \begin{bmatrix} 0\\0\\1 \end{bmatrix} = \underline{i}_{r} = \cos A \qquad (B-18)$$

So far the observability criterion, if the unit vectors from the user to the satellite expressed in the navigation frame are computed, becomes

$$A < A_{max}$$

or

 $\cos A > \cos A_{max}$ (B-19)

or

if $i_{r_D} > \cos A_{max}$, the satellite is observable if $i_{r_D} \leq \cos A_{max}$, the satellite is not observable

Since we arbitrarily selected for our study the minimum elevation angle of ten degrees the above criterion requires the azimuth component of this unit vector to be greater than the value of $\cos 80^\circ = 0.174$.

$$i_{r_{D}} > 0.174$$
; $A = 80^{\circ}$ (B-20)

Total deployment consists of three rings or "constellations" of six satellites each. The satellite orbits are assumed to be planar and circular; in fact, the orbital speed and altitude and thus the orbital period of all satellites is assumed constant. Furthermore, since global coverage is desired, the satellites on any of the three rings are equally spaced; thus, the circular are between any two adjacent satellites on a ring subtends a central angle of sixty degrees ($6 \times 60^{\circ} = 360^{\circ}$). The satellite identification code used is a two-digit code, the first digit denoting the particular constellation-ring (1, 2 or 3) and the second digit indicating the particular satellite (1 through 6) among the six on the denoted ring. As an example, satellite 32 is the second satellite on the third ring.

In order to specify the orientation of any one satellite with respect to the Earth-fixed frame, three parameters are required. The most convenient parameters are the Fuler angle, from which the direction cosines or unit vectors to the satellite may be determined. This process is explicitly described in [Ref. 11] and here we will use directly the result for the unit vector from Earth to satellite in Earth coordinates.

$$\mathbf{\underline{r}_{s}}^{e} = [a_{13}, a_{23}, a_{33}]^{T}$$
 (B-21)

where

 $a_{13} = \sin \zeta \sin \xi$ $a_{23} = -(\sin n \cos \zeta + \cos n \sin \zeta \cos \xi) \qquad (B-22)$ $a_{33} = \cos n \cos \zeta - \sin n \sin \zeta \cos \xi$

and the three Euler angles are ξ , η , ζ .

The initial conditions are the constant orbital parameters of the satellite orbits are given in the following two tables. Note that m refers to the mth satellite on the designated n ring; for example, the entry of 2m represents the remaining five satellites of the second ring. The missing entries from the table, (--), are dependent upon the initial values of the Euler angles ξ , n and ζ which are specified. Finally the latitude and longitude values refer to the ground track of the satellites.

TABLE IX

ORBITAL DESIGN CONSTANTS

Orbital Period	12 nours
Angle of inclination	63 ⁰ (all three rings)
Altitude	11,000 n. miles
Separation arc-angle	60° (6 x 60° = 360°)
Ring spacing arc-angle	120° (3 x 120° = 360°)

TABLE	2
-------	---

SATELLITE INITIAL CONDITIONS

Satellite #	Initial Latitude	Initial Longitude	Angle ç _o
11	0°	0°	0°
1m			-60(m-1)
21	0 ⁰	120 ⁰ (E)	0°
2 m			-60(m-1)
31	0 ⁰	-120 ⁰ (W)	0°
3m			-60(m-1)

Now the sequence of equations required to compute the unit vectors for each of the 18 satellites is presented.

$$\xi = 63^{\circ}$$

 $n = 120^{\circ}(n-1) - \omega_{ie}t$ (B-23)
 $\xi = -60(m-1) + Ct$

where

m = satellite designator (1 through 6)
n = ring designator (1, 2 or 3)
w_{ie} = rotational speed of earth = 15^o/h = 1^o/240 sec
C = orbital speed of the satellite

$$C = G_e/r_s = \frac{2r_s \cdot n}{T} = 2.1 \text{ n.miles/sec}$$

Using the Euler angles the components of the unit vectors of the satellite-earth range, $\underline{r_s}^e$, are computed [Ref. 10, 11].

^a 13		sin ç sin ξ	
a ₂₃	2	-(sin $\eta \cos \zeta + \cos \eta \sin \zeta \cos \zeta$)	(B-24)
^a 33		cos n cos ζ - sin n sin ζ cos ξ	

The ground track latitudes and longitudes are given by

Latitude
$$\theta$$
 = arc-tan $(a_{13}^2 / (a_{23}^2)^2 + (a_{33}^2)^2)$ (B-25)

Longitude
$$\Lambda = \operatorname{arc-tan} \left(-\frac{a_{23}}{a_{33}}\right)$$
 (B-26)

The required components of the unit vector of the usersatellite range, \underline{r}^n , in navigation coordinates may now be computed.

$$\underline{\mathbf{r}}_{\mathbf{s}}^{\mathbf{n}} = \underline{\mathbf{r}}_{\mathbf{s}}^{\mathbf{n}} - \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{R} \end{bmatrix} = \underline{\mathbf{c}}_{\mathbf{e}}^{\mathbf{n}} \underline{\mathbf{r}}_{\mathbf{s}}^{\mathbf{e}} - \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{R} \end{bmatrix} = \begin{bmatrix} \mathbf{r}_{\mathbf{N}} \\ \mathbf{r}_{\mathbf{E}} \\ \mathbf{r}_{\mathbf{D}} \end{bmatrix}$$
(B-27)

$$r = (r_N)^2 + (r_E)^2 + (r_D)^2$$
 (B-28)

$$\frac{i_{r_{n}}}{n} = \frac{r^{n}}{r} = [i_{r_{N}}, i_{r_{E}}, i_{r_{D}}]^{T}$$
(B-29)

The observability-criterion requires

 $i_r > \cos 80^\circ = 0.174$ (B-30)

A sample output from the computer program for the observability-criterion is included in the next pages listing the satellites which are in-view at a particular time instant. The output table presents in seven columns the most important calculated data. Column 1 contains the satellite number according to the previously specified code. Columns 2, 3 and 4 contain the north, east, and azimuth components of the unit vector under consideration. Columns 5 and 6 give the ground track latitude and longitude for each satellite. Finally column 7 gives the observability result denoting with "O.K." the satellites which fulfill the criterion and with "--" those satellites which do not fulfill the criterion.
