PREFACE

The Avionics Software Support Cost Model is a new step forward in an attempt to estimate the cost of maintaining onboard embedded computer software. SYSCON Corporation is pleased to be a part of this effort and to nave an opportunity to explore new areas to apply its expertise. SYSCON would like to offer its gratitude to the Air Force for its patience, understanding, and guidance. In particular SYSCON wishes to extend a special thanks to Mr. Dan Ferens, the Avionics Laboratory Project Monitor, for his continuous help in bringing this contract to a successful conclusion.

SUMMARY

For some time now the Air Force has become acutely aware of the ever escalating costs for maintaining embedded computer software. Such costs are necessary to keep onboard avionics systems completely up-to-date with users' requests. To accomplish this, each software system is currently provided with its own uniquely qualified staff. The sole responsibility for these people is to design, develop, integrate, test, and document the software on a continuing basis. The Air Force is now attempting to better control the costs of providing this vital support function.

By studying the factors which affect the costs of maintaining embedded computer software, the Air Force hopes to develop, support, and computerize a methodology to accurately predict these costs. To accomplish this, SYSCON Corporation has developed the Avionics Software Support Cost Model (ASSCM). The ASSCM is the result of more than two years of work. It is an interactive model that projects annual software support costs for various proposed software configurations during the early design phase of system development. It bases its cost projections on a unique algorithm specifically designed to utilize as much of the available historic data as possible. To complement this data, the algorithm also relies on subjective information obtained from a large group of individuals intimately familiar with software support and its costs.

This final report describes the work effort and provides the information necessary to understand, use, and, perhaps, update the ASSCM.

これのないとなるとなっているとことととう

- AND THE WAR STATE OF THE STAT

1 SCOPE

1.1 Purpose

This final report provides the necessary information to support the development, implementation, use, and understanding of the Avionics Software Support Cost Model (ASSCM). This model was designed according to the stipulations and guidelines of the Avionics Laboratory at Wright-Patterson Air Force Base (WPAFB) by SYSCON Corporation under contract number F33615-80-C-1157.

1.2 Functional Summary

The ASSCM is a predictive model which enables the user to estimate the support costs associated with embedded computer software for avionics systems. The model is applicable to a wide variety of avionics computer software; specifically, operational flight program (OFP) software, airborne communications/electronics (CE) software, and airborne electronic warfare (EW) software for these programs. The model does not address software acquisition costs, nor the costs incurred by the users at operational commands for operating the software.

The season

THE WARRANT OF THE

3 OVERVIEW

The ASSCM was developed over a 27 month period from September 1980 through November 1982. During this time a comprehensive effort to understand, evaluate, and project embedded computer software maintenance costs was completed. This effort included the following major milestones:

- Review
- Methodology Development
- Data Collection
- Data Organization and Analysis
- Algorithm Development
- Computerization
- Model Validation
- Documentation

3.1 Review

This task lasted approximately seven months and included a review of all applicable documents and current software maintenance procedures. During this time, discussions were held on site at various Air Logistic Centers (ALC's) with Air Force personnel.

3.2 Methodology Development

This task concerns the development of the model algorithm to be used by the computer for projecting costs. The methodology that was ultimately used was derived specifically as a result of the review process. It reflects a simulation of real world software maintenance procedures as well as a pragmatic approach designed to compensate for the limited amount of available data.

Salar Carried Comment

3.3 Data Collection

As a result of the formulated methodology, a two-phased data collection effort was initiated. Phase I consisted of t collection of historical data for each system currently past the Program Management Responsibility Transfer (PMRT) date. A Phase I questionnaire was designed to obtain the software support costs expended as well as information about the characteristics associated with the software. A Phase II questionnaire was drawn up to obtain certain subjective information about those characteristics. Because of the limited historic data available, subjective data was provided by Air Force personnel on how changes in certain characteristics affect software support cost incurrence.

3.4 Data Organization and Analysis

The data collected from the field was coded and edited so that it could be analyzed for use by the model. The cost information was normalized to remove individual differences caused by extraneous factors (physical location, command decisions, salary steps, inflation etc.). The characteristics information was simply edited for completeness and summarized. Finally, the subjective information was inputted into a computer. Using a statistical package, arithimetic equations and functions were derived which reflect the trends in the answers provided by the respondents.

3.5 Algorithm Development

An algorithm utilizing the information collected was established to project software maintenance costs. The algorithm started with the historical costs and characteristics as the baseline data. The costs were then adjusted according to the characteristic values of the system described by the model

user. The adjustments were accommplished by applying the derived modification factors and functions.

3.6 Computerization

The model algorithm, normalization factors, modification factors, and other necessary information was programmed into a computer. The computer automated the process by which the user may offer his own support software characteristics and facilitated the thousands of computations necessary to complete the cost projection methodology.

3.7 Model Validation

The model was validated by inputting the characteristics of three existing systems whose costs were not used in the model development. The costs projections were compared with the actual costs and the major discrepancies were examined and explained.

3.8 Documentation

All of the information required to develop, implement, and use the ASSCM belongs to the Air Force. An audit trail to support all of the data utilized by the model, as well as the algorithm itself, is provided in this document as well as other publications provided to the Air Force. See also the referenced documents in Section 2.

- The state of the

4 MODEL DEVELOPMENT

4.1 Review

The review period enabled SYSCON personnel to become familiar with how current software maintenance costs are generated, the procedures and problems associated with software maintenance, existing data available, and current methodologies used for estimating these costs. The review consisted of data gathering trips to three ALC's and a comprehensive review of all documents written heretofore related to the subject of projecting costs for maintaining embedded computer software. The three trips were designed to obtain any available data or documents which might by useful and to find out as much as possible about software maintenance costs and the factors which affect those costs. The dates, destination and SYSCON personnel involved are summarized below:

Date	<u>Destination</u>	Systems Discussed	<u>Personnel</u>
9/22/80	China Lake, CA	A-7	J. Cyr
11/3/80-11/7/80	OC-ALC	E-3A -	T. Pavlick, J. Murray
1/12/81-1/16/81	SM-ALC	F-111F, F-111D FB-111A	J. Murray, B. Johnson
2/9/81-2/13/81	WR-ALC	APR-38, ALQ-155 ALQ-131, ALR-69 ALR-46, ALR-62	W. Gagner, R. Bentley, J. Murray

The major conclusions that resulted from this review are summarized below:

 The ALC's collect cost data independently, providing a nonstandard means for summarizing information for all ALC's.

- Free Contractor of the

- There were too few systems with post-PMRT experience to develop statistical cause-and-effect relationships between costs and software characteristics.
- Air Force personnel were very interested in estimating software support costs but had no formal means for doing so at this time.
- Labor cost data was collected uniformly on Form 75 for all ALC's;
 nowever, this information was projected (not actual) and could not
 be used to support the ASSCM in its present form.
- Indirect labor costs and support equipment costs are not broken out by system, nor are the costs available from one source.
- Where cost information exists for a specific system, summarizing it would be an extremely time-consuming and costly effort, perhaps reaching a point of diminishing returns.
- There are certain software characteristics which diractly impact upon software maintenance costs. These include program size, language, complexity rating, structure, etc. and are discussed in greater detail in section 4.2.
- An algorithm uniquely capable of simulating a situation wherein limited available data is required to project software maintenance costs would best achieve the Air Force's goals.

SYSCON's conclusions about the lack of available data were not encouraging insofar as the development of a computer model based on statistically reliable manipulations of a comprehensive data base. Prior to suggesting an alternative methodology, SYSCON presented its summary of data collection problems. This is provided in APPENDIX A.

As a result of these observations and conclusions, SYSCON developed an

- - TO BEALT OF

alternative pragmatic approach for estimating support costs of future embedded computer systems. This was presented on March 19, 1981 in a concept paper.

(See Applicable Document No. 3)

4.2 Methodology Development

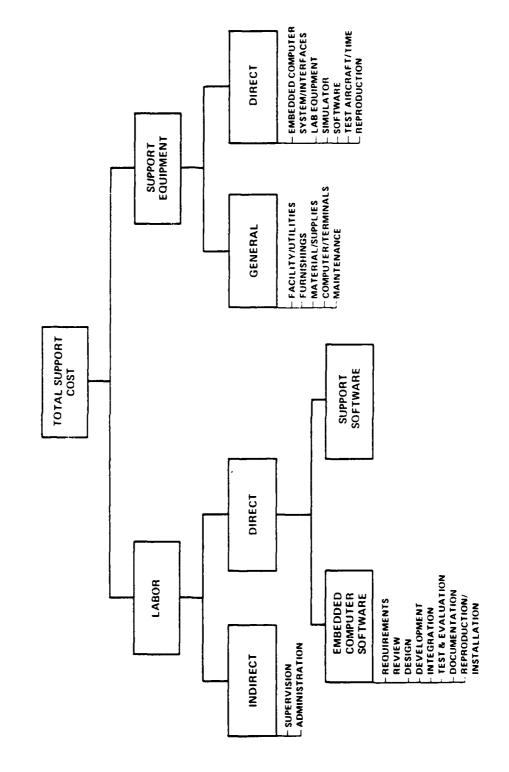

After the data collection trips and the information received was digested, SYSCON developed a unique methodology upon which to base the model. This methodology makes use of the data currently available while providing a means to logically project and support cost estimates.

The first task was to develop a standardized means for collecting cost information. This effort resulted in the work breakdown structure (WBS) shown in FIGURE 1. This WBS enables one to collect cost data for all systems such that a consistent definition of costs can be assured. This formed the basis from which costs were collected and projected, enabling costs for the various systems to be properly and reliably compared.

Associated with the costs collected for supporting the embedded computer software of any one system are the characteristics that describe that system. As a result of the review effort, sixteen factors were hypothesized to affect costs. These factors, as well as some additional descriptive information, are listed in FIGURE 2. Depending upon the value given for each of the characteristics, software support costs could be expected to increase or decrease in a predictable fashion. This forms the basis upon which the methodology is founded.

The general methodology with a specific example was provided to the Air Force in Applicable Document No. 3. It relies on historical information from current systems to constitute the baseline data. It then assumes that relationships between costs and changes in the characteristics that describe

the software can be quantified and applied to the historic costs to form a new, projected cost estimate. Costs are defined according to the WBS and are adjusted according to arithmetic modification equations. The modification equations are to be derived from data collected from Air Force personnel who are intimately familiar with software maintenance.

4.3 Data Collection

To accomplish the data needs to support the methodology, two separate questionnaires were designed. The Phase I questionnaire seeks specific information about a particular system as well as general information which might apply to several systems. FIGURE 3 lists the information requested by the Phase I questionnaire. It should also be noted that the Phase I questionnaire was completed by only one person per system, usually the lead engineer or supervisor. Where the general information is not known, additional personnel (usually administrative) were contacted at the various ALC's. A copy of the Phase I questionnaire is provided in APPENDIX B.

The Phase II questionnaire is designed to obtain subjective information. This questionnaire was to be completed by as many software support engineers as possible. The objective is to find out how changes in certain characteristics affect labor costs and to derive mathematical functions to reflect the overall trend of answers. FIGURE 4 provides the information about which expert judgment was requested. The Phase II questionnaire is provided in APPENDIX C.

4.4 Data Organization and Analysis

Data was collected using the Phase I and Phase II questionnaires from all known sources where embedded computer software was being maintained. FIGURE 5 summarizes the location, systems, and type of data collected.

As stated above there are two distinct types of data: historical and subjective. The historical data for each system includes actual costs expended during the most recent block change period as well as various descriptive information about the software and the people maintaining the software. This information was summarized and edited for completeness. The data for seven systems was deemed sufficiently complete. These systems eventually became the baseline data for the ASSCM. Data for three other systems were used to facilitate the model validation.

Phase II data was collected from thirty-nine individuals who were currently maintaining embedded computer software. These people exhibited varying degrees of experience and provided a wide spectrum of responses from which to derive trends. Each of the questionnaires was admininstered by

I with the second of the

SYSCON personnel to maintain as consistent an understanding of the questions as possible. The results were coded, edited, and read into a computer for final analysis.

4.4.1 Historical Data.

The historical data was usually obtained from either the lead engineer or the supervisor for each software support staff. Once all of the questions were answered, the descriptive data was simply summarized. The cost data, nowever, had to be normalized to remove the exogenous factors which affect the costs for the various systems differently.

For example, a GS-11 employee's annual salary may vary considerably depending on his or her step. To compensate for this exogenous cost difference, an average annual salary for each grade was derived. Another example concerns the number of personnel managed by a supervisor. For one group the ratio might be ten workers per supervisor. For another group it might be six. The model assumes an average figure.

All of these normalization factors and their FY 1981 values are provided in TABLES 1-A through 1-D

when determining the actual values of the normalization factors, SYSCON employed an expert panel approach to determine the most reasonable values. This was necessary because the data available was limited and not subject to statistical analysis. It should be noted that the explanations provided below include the input and judgement from several individuals. Thus, a particular value that might be referred to as an average may not actually equal the arithmetic average of all the data available. It simply reflects the concensus of the entire group for the most reasonable figure.

1k = NUMBER OF LINES OF CODE ON ONE PROM (IN THOUSANDS)

ᅬ	.25	.50	1.00	2.00
FIRST YEAR	BEFORE 1981	1981-1982	1983-1985	AFTER 1985

See APPENDIX D for a summary of the data from which most of the decisions were based. A discussion of each normalization factor follows.

4.4.1.1 Organic Labor Cost/Manmonth By Grade

The organic labor cost/manmonth by grade is assumed to be the same for all personnel within each grade. This was determined separately for civilian and military grades and is used to normalize the historical direct labor cost for maintaining the software for the most recent block change. See TABLES 2-A and 2-B for the derivation of these normalization factors.

4.4.1.2 Contractor Labor Cost/Manmonth

The contractor labor cost/manmonth is assumed to be \$7,000 for fiscal year 1981. This figure is based on the historical data collected which indicated a range of \$4500 to \$10,000. The chosen figure seems to best reflect the average for contractors, either on-site or off-site.

The contractor labor cost/manmonth is used to convert contractor manmonths to contractor costs. This normalization is necessary to account for the varying rates that are charged by different contractors.

4.4.1.3 Supervision Ratio

The supervision ratio is the inverse of the employees per supervisor. Actual data indicated that supervisors managed from three to fourteen people. An average figure of 7.7 was assumed to reflect all of the ALC's. Thus, the supervision ratio is computed as follows:

1 + 7.7 = .13

 $[\]frac{2}{\text{Previous}}$ column multipled by 1.50. Overall civilian's benefit factor is about 1.33. Since military benefits include housing and food allowances, 1.50 is used as an estimate.

 $[\]frac{3}{4}$ Assumes 0-1

 $[\]frac{4}{\text{Assumes}}$ average of 0-4, 0-5, and 0-6 equally weighted.

4.4.1.4 Administrative Ratio

The administrative ratio is similar to the supervision ratio but reflects the number of administrative personnel required to serve the software support staff. Actual data showed that the number of workers per supervisor and administrator was nearly the same. Therefore, the administrative ratio was assumed to be the same, i.e, .13.

4.4.1.5 Supervision Cost/Manmonth

The supervision cost/manmonth is assumed to be the same for all supervisors. Since this person is usually a grade GS 13, the average cost/manmonth for this grade is assumed to apply. As shown in TABLE 2-A, the figure is \$4,390.

4.4.1.6 Administrative Cost/Manmonth

The administrative cost/mammonth is assumed to be the same for all administrators. Since this person is usually a secretary below a grade 9, the average cost/mammonth for a grade below GS 9 applied. As shown in TABLE 2-A, the figure is \$1,847.

4.4.1.7 Administrative Complexity Function

The administrative complexity function is designed to reflect the increase in administrative costs due to the monitoring of outside contractors. This equation is derived from subjective information requested as part of the Phase I questionnaire. The question reads as follows:

Describe the relative increase, if any, in administrative costs caused by increasing the amount of work contracted. Assume that if 0% of the work is performed by contractors, the value is 1.00. For example, if you feel that contracting 50% of the work would increase administrative costs by 20%, you would write 1.20 below the 50 percent column.

					cted
Dalatina imanaga in	0	25	50	75	100
Relative increase in administrative costs	1.00		_		

The average of all answers reflect the following relative cost increases:

Incorporating this information into a continuous function results in the following equation:

4.4.1.8 Inflation Factors

The inflation factors are used to normalize costs such that costs referring to different periods of time can be compared. These factors remove the impact of price increases directly tied to inflation.

The inflation factors were provided by the Air Force and are current for October 1981. For all years after 1986 an annual inflation rate of 9.6% is assumed.

4.4.1.9 T&E Ratio

The T&E ratio is used to estimate the number of actual hours in the air for testing the new software after changes have been completed. The T&E ratio is defined as the number of manhours required for testing and evaluating the software (in the lab) divided by the number of hours required to test the software actually onboard the aircraft (in the air).

THE PARTY OF THE P

The average figures selected are estimated from the historical data available. Because it appears that system type impacts the amount of T&E required in the air, three separate factors are used. These are listed below:

System Type	T&E Ratio
OFP:	3.0%
EW:	5.0%
CE:	3.5%

4.4.1.10 Cost/Flight Test Hour By Aircraft Type

The cost/flight test hour by aircraft type represents the nourly cost for testing the updated embedded computer software under actual circumstances.

This is the cost of flying the airplane as well as using the test range.

The historical data indicates varying costs per hour for testing depending upon the type of aircraft being used. The amounts selected as most representative are shown below:

		Air	craft Typ	<u>e</u>
	Cargo	Bomber	Fighter	Surveillance
Cost/Flight Test Hour	\$2,000	\$5,000	\$2,000	\$6,000

4.4.1.11 Cost/Reproduction By Medium

The cost/reproduction by medium is used to estimate the cost necessary to duplicate the updated software and install it on the aircraft in the field.

There are three primary media for copying the software: mylar tape, PROM, and magnetic tape. The unit medium costs are \$35, \$20, and \$17, respectively.

Associated with each of these media is an undefined factor called the medium factor. The medium factor is used to convert program size to an

A 34 34

average number of tapes or PROMs required per fielded system. The medium factor is .12 for mylar tape. This indicates that only a portion of the entire role of mylar tape is required per system. For PROMS the medium factor is related to the number of lines of code and a constant, K, which takes into account technological changes over time. The medium factor is:

Medium Factor (PROM) = $\frac{\text{Lines of code X 1.1}}{\text{K}}$

Where K = .25 before 1981

K = .50 between 1981 and 1982
K = 1.00 between 1983 and 1985

K = 2.00 after 1985

This factor divides the lines of code by the amount of code able to fit on a PROM, while assuming 10% spoilage. The amount of code able to fit on a PROM is expected to increase over time, as indicated by the time-dependent values of K.

The medium factor for magnetic tape is different depending on the system application. The number of tapes necessary on average for an OFP application is 2. For CE, the number of tapes required is significantly higher. The value chosen is 25.

4.4.1.12 Space/Person

The space/person normalization factor is used to estimate the amount of building space required once the number of people has been estimated by the model. For technical personnel, the number of square feet per person is 275. This includes space for lab equipment, desks, chairs, shelves, floors, and anything else.

Since supervisors do not necessarily require space for equipment, a smaller space is required. An office of 10 feet by 13 feet or 130 square feet

- The organism of

is assumed to be representative.

4.4.1.13 Building Cost/Square Foot

The building cost/square foot is used to estimate the facility cost for sneltering a software support staff. Although building costs vary considerably all over the country, \$136 per foot is assumed to be representative for this nonrecurring cost.

4.4.1.14 Utility Cost/Square Foot

The utility cost/square foot is used to account for utility costs associated with a building. This recurring cost varies considerably depending on the climate experienced by a particular region. The figure chosen to be most representative is \$1.20.

4.4.1.15 Furnishing Cost/Person

The furnishing cost/person accounts for the nonrecurring costs of supplying employees with their everyday needs: desks, chairs, filing cabinets, etc. An amount of \$680 is assumed.

4.4.1.16 Materials and Supplies Cost/Person

The materials and supplies cost/person includes recurring costs necessary to supply each employee. This includes pens, pencils, paper, desk pads, paper clips etc. The amount assumed is \$700 per year.

4.4.1.17 General Computer Cost/Person

The general computer cost/person is used to estimate the computer

··· 产生的自然的自然的

hardware and other peripheral costs that are assigned to, and used by, more than one staff of people. This nonrecurring cost is assumed to be \$20,000.

4.4.1.18 Hardware Maintenance Cost Ratio

The hardware maintenance cost ratio is used to estimate the recurring cost of maintaining the computer, peripherals, and other lab equipment. Based on the data available it appears that maintenance costs are approximately 10% of the original hardware acquisition cost.

4.4.2 Subjective Data.

The subjective data is obtained from members of the software support staffs at each of the locations visited. These people work with the embedded computer software everyday. They have an indepth knowledge of the procedures required and know better than anyone else how certain characteristics in the software affect their time.

The Phase II questionnaire was given to several people at once and adminstered by SYSCON personnel. In this way, a consistent understanding of the questions would be relayed to the respondents to insure reliability of answers to the maximum extent possible. Thirty-nine questionnaires were completed, thirty-six by Air Force personnel. These included both civilian and military. APPENDI F lists the names of the respondents and their locations.

The approach used to obtain the subjective information is known as the Delphi Technique. Generally, the Delphi Technique is applicable to situations where real answers are unknown--usually some sort of prediction of future events is required. This is precisely the situation here. The objective is to predict now changes in certain system characteristics will impact on costs.

- PERSONAL PROPERTY OF THE

The Delphi Technique calls for the opinions of expert panelists. The original responses are tallied and summarized. The panalists are then notified of the average answers of the group as a whole. Each has an opportunity to change any of his/her answers based on this additional knowledge. The final answers are then tallied and readied for analysis.

All of the Phase II responses were received by December 1981. The answers were coded and fed into SYSCONs' Hewlett Packard 3000 computer. Next, the numbers were averaged and summarized. Each respondent was then sent a computer-generated letter indicating how his answers compared to the groups' averages. A sample of this letter is shown in APPENDIX G. Each respondent was given the opportunity to make any changes and forward the results back to SYSCON. All questionnaires were completed and returned by February 1982.

The data changes were made so that the files could be updated. The files were then fed into a statistical package to ensure that the new answers could be edited for completeness and consistency and readied for statistical analysis.

There were two types of statistical analyses performed on the data. First, the answers were simply averaged to derive the general trend. This was all that was necessary for several of the questions that simply asked for ordinal $\frac{1}{2}$ (ranking) data.

The other questions asked for ratio type data, which is susceptible to more sophisticated statistical analyses. For these questions, linear and

1/There are four types of data: nominal, ordinal, interval, and ratio. Nominal data, such as the numbers on the back of baseball players' uniforms, cannot be maniputed. On the other end of the scale is ratio data. An example is the number of name runs hit by baseball players during the year. Ratio data can be manipulated such that adding or dividing two totals is meaningful. For more information on this subject see any standard statistical test book, including Research for Marketing Decisions, Paul E. Green and Donald S. Tull, Prentice-Hall, Inc., Englewood Cliffs, N.J., 1970, pages 174-181.

nonlinear regression analysis was used to derive arithmetic equations that statistically represent the data. This also provided statistical criteria for measuring now well the equations reflected the data. In each case an exponential and a linear relationship were tested. Where further testing was deemed necessary, a logarithmic equation form was tried. The shape which exhibited the best fit according to the statistical criteria was chosen. Computer printouts of the statistical results have been provided to the Air Force under separate cover.

The results of the regression analyses discussed above are shown in TABLE 3. TABLE 4 summarizes the modification factors for those characteristics not susceptible to regression analysis. Each derivation is discussed below.

4.4.2.1 Lines of Code

The question on lines of code is designed to measure now changes in the embedded computer software size affect costs. The hypothesis is that the larger the program, the more difficult to change and update the software, causing costs to increase. As shown in TABLE 3, the shape of equations varies between exponential and a straight line, depending upon the work phase in question.

The cost of maintaining the support software is assumed to be independent of the embedded computer software size.

4.4.2.2 Percent Memory Fill

The percent memory fill is important since as this characteristic approaches 100%, additional lines of code will require some deletion of old code. Obviously, time and costs would increase substantially to accomplish this.

Compression of the

Once the regression equation was selected, a further adjustment was necessary. Since regression analysis assumes a continuous function, the resulting equation reflects a relationship over all possible values for percent memory fill. To compensate for the unnecessary need of concern to reduce program size for low percentages, SYSCON judged that deletion of lines of code does not become important until the percent memory fill reaches 75%. Only as the percentage becomes 75% or greater does this concern become significant enough to affect costs. Thus, percentages of less that 75 are assumed to have no impact on cost causation.

The cost of maintaining the support software is assumed to be independent of the embedded computer software.

4.4.2.3 Percent Timing Fill

The percent timing fill is important for the same reason as percent memory fill. As the percent reaches 100%, additional program adjustments may be necessary to reduce timing constraints when the software is updated.

The exponential equations were chosen for each of the seven work phases. As with percent memory fill, percentages below 75% are assumed to have no impact on costs. Moreover, the percent timing fill has no effect on the support software maintenance costs.

4.4.2.4 Percent of Work Performed by Contractors

This characteristic is used to estimate costs associated with using outside help to perform the work. The hypothesis is that hiring outside people will cause some duplication of work, as well as additional costs for monitoring the effort.

THE WARRANT AND A ST

The regression equations which best reflected the data indicate a logarithmic shape, except for documentation. For the latter, a linear shape was best.

The equations indicate that costs rise as the percentage of work performed by contractors rises. However, after a certain percentage, perhaps 30%, the amount of rise tends to slow considerably.

With this characteristic, support software costs are expected to change in the same manner as software development costs. However, reproduction/installation costs are unaffected by the percent of work performed by contractors.

4.4.2.5 Year of Support

This characteristic is designed to account for the time necessary to become completely familiar with the software. The hypothesis is that as time progresses, maintenance cost will decline (all other factors remaining the same).

The equations indicate that costs decrease exponentially as time (year of support) increases. This is indicated by the negative sign in the exponent.

It is also hypothesized that at some time a point of diminishing returns would be reached, whereby further familiarization with the code has no cost impact. SYSCON judged that after the sixth year, this factor will have no impact on cost causation, therefore the questionaire allowed for an impact from this characteristic only for the first six years of support.

The equation for support software is assumed to be the same as derived for the development phase.

The state of the s

4.4.2.6 Number of Fielded Systems

The number of fielded systems has only a small cost effect on software support. However, because the regression equations for this factor are statistically significant, SYSCON allowed the model to incorporate the small effect into its cost estimating algorithm.

This factor has no impact on maintaining the support software.

4.4.2.7 Change Efficiency

The question regarding change efficiency is designed to gain a measure of the amount of work performed compared to the amount of work requested. Thus, change efficiency is the number of changes to be completed by the software support staff divided by the number of changes requested by the user. Its effect on cost is the same for each of the work phases, except requirements review and reproduction, where it is assumed to have no effect.

The equation derived is exponential and shows a significant impact as the amount of work to be completed is increased. This is as expected.

4.4.2.8 Language

The language of the software is expected to impact the costs of software maintenance. The question lists three alternatives and requests opinions as to what extent costs are impacted. The results shown in TABLE 4 are simply the arithmetic means for all who responded to the question. As hypothesized, a program written in a structured-higher order language, rather than assembly language, is shown to reduce substantially the costs of supporting the software, all other factors remaining the same.

The language of the embedded computer software does not affect the cost of maintaining the support software.

4.4.2.9 Development V&V Rating

The development verification and validation (V&V) rating is a measure of now well the software as originally developed performs. As expected, the results of the survey show that maintenance costs will diminish as the development V&V rating improves.

In TABLE 4, for year of support equal to 1, the numbers shown provide the actual computed averages of responses. However, SYSCON hypothesizes that after the third year of support, the support staff has made sufficient changes in the software that the V&V rating would no longer have an impact on the support costs. Thus, after the third year this function reverts to all 1's.

For the year of support equal to 2 and 3, a stepwise adjustment was required to smooth out the reduction of importance for this factor over time. SYSCON judged that 100% of the impact for V&V rating is felt during the first year of support, 35% during the second year, 10% during the third year, and 0% thereafter. Thus, the following equations are used to adjust the originally computed averages:

For values greater than one (unity):

$$(X-1) W + 1$$
 (1)

For values less than one (unity):

$$\frac{1}{(1/X-1)W+1}$$
 (2)

where X = original factor
W = weight (% of full impact)

For equation (1), 1 is substracted from the original factor to obtain the amount of impact. (For example, 1.80 means an 80% increase.) This is then

THE RESERVE OF THE

multiplied by the weight. (That is, 35% of 80% would be 28%). One is then added back to get the new factor. (.28+1 = 1.28).

For equation (2), one must work with the reciprocal to maintain consistency. The logic and explanation is precisely the same. An illustrative example is useful.

Suppose the original factor is 1.80. This represents an 80 percent increase in costs. A second factor to exactly offset this increase is

$$1/1.80 = .555$$

Thus, a .555 factor is precisely an equal and opposite factor that would offset an 80% increase (.555 x 1.80 = 1.00).

Now apply the 35% weighting factor by using equations (1) and (2):

$$(1.8-1)(.35)+1 = 1.28$$

$$\frac{1}{(1/.555-1)(.35)+1} = .7809$$

The 1.28 and .7809 are also equal and offsetting. (1.28 \times .7809 = 1.00)

Using the two equations discussed above and the weights W=.35 for year of support = 2 and W=.10 for year of support = 3, the numbers shown in TABLE 4 can be computed. For example, the 1.41 and .90 for requirements review in the first year of support are modified to 1.14 and .96, respectively, for the second year of support. The computations are illustrated below:

$$(1.41 - 1)(.35) + 1 = 1.14$$

$$\frac{1}{(1/.90-1)(.35)+1} = .96$$

· 医多种 10 全种的 10 10

The rest of the numbers are computed in precisely the same fashion.

Development V&V rating is assumed to have no impact on maintaining the support software.

4.4.2.10 Program Design Rating

The program design rating is a measure of how well the program was supposed to be structured. As expected, the results showed that as the program design structure improves, maintenance costs would diminish.

This factor is not expected to affect support software maintenance costs.

4.4.2.11 Program Implementation Rating

This factor is similiar to program design rating except that it is concerned with how well the program structure is actually implemented. The results are very similar to those of program design rating.

4.4.2.12 Initial Documentation Rating

The initial documentation rating is concerned with how well the documentation is at the time the development software is turned over to the support staff. The hypothesis is that little or no documentation increases support costs and vice versa.

In addition, SYSCON hypothesizes that after the third year of support, this factor diminishes in importance. As the staff reworks the software over time and redocuments the changes, the initial documentation has less and less of an impact on costs. The methodology used to smooth the impact of this factor for the second and third years of support is precisely the same as that explained above for development V&V rating.

5年1日《**教授》**311年4

multiplied by the weight. (That is, 35% of 80% would be 28%). One is then added back to get the new factor. (.28+1 = 1.28).

For equation (2), one must work with the reciprocal to maintain consistency. The logic and explanation is precisely the same. An illustrative example is useful.

Suppose the original factor is 1.80. This represents an 80 percent increase in costs. A second factor to exactly offset this increase is

$$1/1.80 = .555$$

Thus, a .555 factor is precisely an equal and opposite factor that would offset an 80% increase (.555 x 1.80 = 1.00).

Now apply the 35% weighting factor by using equations (1) and (2):

$$(1.8-1)(.35)+1 = 1.28$$

$$\frac{1}{(1/.555-1)(.35)+1} = .7809$$

The 1.28 and .7809 are also equal and offsetting. $(1.28 \times .7809 = 1.00)$

Using the two equations discussed above and the weights W=.35 for year of support = 2 and W=.10 for year of support = 3, the numbers shown in TABLE 4 can be computed. For example, the 1.41 and .90 for requirements review in the first year of support are modified to 1.14 and .96, respectively, for the second year of support. The computations are illustrated below:

$$(1.41 - 1)(.35) + 1 = 1.14$$

$$\frac{1}{(1/.90-1)(.35)+1} = .96$$

- PARTICIPATION AND A TOTAL

For example, the factors for requirements review in the first year of support are 2.84 and .65. This is shown in TABLE 4. These numbers are adjusted for the second year of support as follows:

$$(2.84 - 1)(.35) + 1 = 1.64$$

$$\frac{1}{(1/.65-1)(.35)+1} = .84$$

This factor has no impact on support software maintenance costs.

4.4.2.13 Type of Aircraft

The type of aircraft is judged to affect costs to a lesser degree than originally hypothesized. However, because of the significantly diminished costs associated with cargo aircraft, this factor was retained.

Type of aircraft does not affect support software maintenance costs.

4.4.2.14 Complexity Rating

This factor is a general measure of how complex the software and hardware is. The rating ranges from 1 to 5, with 5 being most complex. The definition for each of the five levels is shown in FIGURE 6.

The complexity factor is important because it has such a pronounced effect on maintenance costs. As shown in TABLE 4, the difference between a complexity rating of 1 and 5 for the software development phase is a factor of seven (3.60/.51 = 7.06).

Complexity is assumed to affect support software maintenance in the same manner as it affects the development phase.

4.4.2.15 Rate of Change

The rate of change is a measure of how difficult it is to keep up with user requests for software changes. It varies from 1 to 5. The definitions are provided in FIGURE 6.

SYSCON hypothesizes that the more stable the code is, the lower the maintenance costs and vice versa. The survey results bear this out.

For support software, the cost impact of this factor is assumed to be the same as for the development phase.

4.4.2.16 Work Efficiency/Skill Level Mix

The work efficiency/skill level mix measures the ability and experience of Air Force organic personnel. The skill level varies between 1 and 5, with 5 referring to the most experienced staff. See FIGURE 6 for the definitions.

This factor is important because experience and familiarity of the code can make a very large difference in the time required to update the software. For example, a staff of skill level mix 5 can be expected to develop new code almost eight times as fast as a skill level 1. (3.68/.48 = 7.7).

The original question in the Phase II questionnaire asks for the impact on cost (not manhours) for the various skill levels. Work efficiency/skill level is a measure of time. Thus, the results from the survey showing relative costs have to be transferred to a measure of time. A two-step process is required.

The first step is to establish an average cost/manmonth for each skill level. This applies to each member of the staff and each member is assumed to be paid the same amount. The methodology to accomplish this is shown in FIGURE 7. The results from this analysis are listed below:

- - - Committee of the

FIGURE 6

DEFINITIONS FOR COMPLEXITY, RATE OF CHANGE, AND SKILL LEVEL

Characteristic		Range of Values
Complexity	1 =	Easy to read code, many similar applications.
	2 =	Time required to gain familiarity with code, many similar applications.
	3 =	Time required to gain familiarity with code, approaching state-of-the-art.
	4 =	Extremely difficult-to-understand code, few similar applications.
	5 =	Extremely difficult-to-understand code, unique application, state-of-the-art.
Rate of Change	1 =	Stable code, changes required very infrequently, minimal staffing required.
	2 =	Infrequent changes required on a periodic basis, staffing assigned on a part-time basis.
	3 =	Changes required on a periodic basis, staffing requirements fairly constant.
	4 =	Frequent changes, changes require immediate attention, full-time staff required plus additional personnel for perturbations.
	5 =	Changes required continuously, full-time staff plus additional personnel have difficulty keeping up with user requirements.
Skill Level Mix	1 =	Predominantly inexperienced, junior personnel unfamiliar with the software system.
	2 =	Variety of personnel with limited working knowledge of the software system.
	3 =	Typical personnel with some experience with the software system, mix of junior and senior personnel.
	4 =	Predominantly senior personnel with a good working knowledge of the software system.
	5 =	Highly experienced personnel with a good working knowledge of the software system.

GS 12	3,576
GS 13	4,390

 $[\]frac{1}{2}$ Factors determined subjectively

Skill Level	Cost Manmonth
1	\$2,785
2	3,005
3	3,325
4	3, 638
5	3,922

The second step is to adjust the averages of the answers obtained from the respondents who answered the Phase II questionnaire. These averages are shown in TABLE 5. Costs can be converted to time by dividing the relative cost by the cost per mammonth. That is:

Taking a ratio of the manmonths for two skill levels will then result in the relative differences in manmonths or time. An equation can thus be derived using the following notation:

 C_x = Relative Cost/Marmonth for Skill Level x (x=1,2,...5)

 $I_x = Relative Cost for skill Level x$

 T_x = Relative Time required to perform the task for skill level x

$$\frac{T_{x}}{C_{x}} = T_{x}$$

If skill level 3 is considered the base from which all other skills are to be compared, then $T_{\rm X}/T_{\rm 3}$ will provide a new index for time, <u>i.e.</u>, work efficiency/skill level mix.

For example, take the first number in TABLE 5, 2.68. The relative time required for a skill level 1 staff to complete requirements review is:

$$\frac{2.68}{$2,785} = .0009623$$

The relative time required for a skill level 3 staff to complete the same task is:

$$\frac{1}{\$3,325}$$
 = .00030075

Comparing the skill level 1 staff to the base staff results in the relative work efficiency:

$$\frac{.0009623}{.00030075} = 3.20$$

Thus, the skill level 1 staff will take 3.20 times as long as the skill level 3 staff.

In general the derived equation which provides the results shown in TABLE 5 is:

$$\frac{T_x}{T_3} = \frac{I_{x/}C_x}{I_{3}/C_3}$$

$$\frac{T_x}{T_3} = \frac{I_x/C_x}{1/3325}$$

$$\frac{T_X}{T_3} = \frac{3325}{C_X} \cdot I_X$$

For support software, the work efficiency for software development is assumed.

4.5 Cost Projection Algorithm

The algorithm designed for the ASSCM encompasses the Phase I historical data, the Phase II subjective data, and the work breakdown structure to project costs. The historical data is used to derive the normalized baseline data. Independently, the subjective data is used to derive modification factors. The modification factors are applied to the baseline data twice: once to reflect representative characteristic values, and again to reflect the characteristics specified by the model user. A schematic illustration of this relationship is provided in FIGURE 8.

As shown in FIGURE 8, there are three major areas in which computations take place. First, the historical data is normalized. The normalization factors are applied to the historical data to remove outside, exogenous factors to the extent possible. Secondly, the historic characteristics which describe the software are changed to reflect a more typical system. To accomplish this, the modification factors are applied to the normalized baseline data to obtain the representative baseline data. Finally, the representative characteristics are changed again, according to the values selected by the model user. Applying the modification factors again, this time to the representative baseline data, results in the final cost projections being sought by the user. See FIGURE 9 for a schematic view of the relationship among data bases.

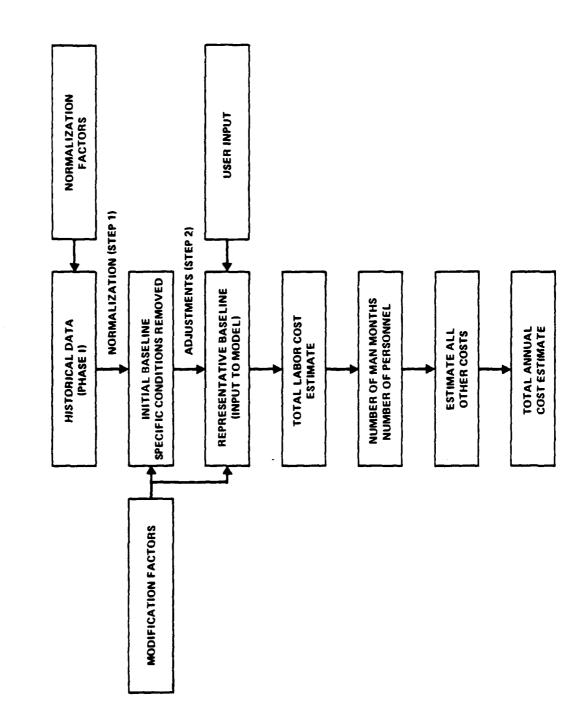

A discussion of now each of the three data bases is derived follows.

4.5.1 Normalization

From the historic data collected, seven systems were chosen to comprise the baseline data. Each represents a different application of either operational flight program (OFP) software, airborne communications/

- Problem Control

FIGURE 8 MÓDEL ALGORITHM

MODIFICATION FACTORS PROPOSED SYSTEM COSTS & CHARACTERISTICS

electronics (CE) software, or airborne electronic warfare (EW) software. The actual systems and their applications are listed below:

System	Type	Application
F-16 FCC	OFP	Fire Control
F-111F	OFP	Navigation, Weapon Delivery
A-7	OFP	Navigation, Weapon Delivery, Fire Control
APR-38	EW	Integrated System
ALQ-131	EW	Jammer
ALR-62	EW	Receiver
E-3A	CE	Command and Control

The first step in the algorithm is to normalize the historical data from these systems. Using the normalization factors discussed in sections 4.4.1.1 through 4.4.1.18, the annual cost for the most recent block change of each system is recreated. A computer printout for the seven systems illustrating these costs is provided in APPENDIX H. The historic characteristics which these costs reflect are shown in TABLE 6.

4.5.2 Representative Baseline

The representative baseline data is generated to allow the cost projections to start with a data base that is more reflective of a future system than, perhaps, the one system for which data happened to be available. This will enable the model to more easily handle a wide range of characteristic values, while reducing the risk of error caused by estimating the cost impact of changing a characteristic value from one extreme to another.

NOTE: SEE FIGURE 2 FOR THE MEANING OF EACH NUMERICAL VALUE

The characteristics of a typical system for each of the seven baseline applications were generated from the Phase II questionnaire. There, each respondent was asked to provide his judgment as to the representative value for each of the sixteen characteristics. After tabulating the results, SYSCON selected values from the available information to describe the hypothetical representative systems. The values chosen are shown in TABLE 7.

Using these characteristic values, the algorithm applies the modification factors to the historic baseline cost data. Representative cost projections are obtained by using the following equation:

$$R_{x} = S_{R} \cdot M_{x} \cdot P_{x} (H) \cdot P_{x} (L)$$

where R_{χ} = Representative baseline annual direct labor cost for phase x $(x = 1, 2, 3, \dots8)$

 S_R = Cost/Manmonth for the skill level of the representative system.

 M_{x} = Initial baseline annual manmonths required for phase x

 $P_X(H)$ = Function of modification factors whose overall effect is to increase costs for phase x

 $P_X(L)$ = Function of modification factors whose overall effect is to decrease costs for phase x

As shown by the equation above, the representative costs are computed independently for each phase (requirements review (x=1), design (x=2), development (x=3), integration (x=4), T&E (x=5), documentation (x=6), reproduction/installation (x=7), and support software (x=8)). The algorithm starts with the historic manmonths (M_X), modifies this figure based on the

TO THE REAL PROPERTY.

cumulative change in the characteristic values ($P_X(H)$ and $P_X(L)$), and finally converts manmonths to dollars. This is accomplished by multiplying by the cost per manmonth for the representative skill level (S_R). Another way of viewing these computations is illustrated in FIGURE 10.

The historic manmonths are provided by APPENDIX H; they are also repeated in TABLE 8 for the reader's convenience. The possible values for S_R are provided on page 51 above. $P_{\chi}(L)$ and $P_{\chi}(H)$, however, require further explanation.

The functions $P_X(L)$ and $P_X(H)$ are derived from the modification factors. They are used to quantify the impact on manmonths directly caused by a change in one or more system characteristics. These changes are measured in relative rather than absolute terms. Thus, the modification factors are always a ratio of computations which result in the relative impact on manmonths of changing a characteristic from one value to another.

For example, if the language is FORTRAN for the historic system and a structured higher order language for the representative system, then the separate impact on manmonths for program development is computed as follows:

$$.62/.67 = .925$$

The numbers .62 and .67 are taken right out of TABLE 4 under language.

Manmonths would be expected to decrease by 7.5%. Thus, the ratio of modification factors for any given characteristic is the relative impact on manmonths from changing the value of that characteristic from the historical value to the representative value.

 $P_{\chi}(H)$ accounts for the combined effect of those factors which increase costs. $P_{\chi}(L)$ accounts for those which decrease costs. The derivation of $P_{\chi}(H)$ and $P_{\chi}(L)$ is explained in the following paragraphs.

- -- FREE PROPERTY -

Assume that $F_{i,x}$ is defined to be the relative impact on manmonths in phase x caused by modifying system characteristic i. (i refers to any of the sixteen modification factors. See TABLES 3 and 4 above.) $F_{i,x}$ is the ratio of the modification function's value after the change, divided by the modification function's value before the change. Written algebraically,

$$F_{i,x} = A_{i,x}/B_{i,x}$$

where $A_{i,x}$ = The value of each modification factor i for phase x using the characteristic value of the representative system

 $B_{i,x}$ = The value for each modification factor i for phase x using the characteristic value of the historic system.

For example, if lines of code is 30K for the representative system and 24K for the historical system, the ratio of the modification factors for the first two phases (requirements reviews and design) is:

$$F_{1,1} = \frac{.0255 (30) + .587}{.0255 (24) + .587} = 1.128$$

$$F_{1,2} = \frac{.239 (30) .539}{.239 (24) .539} = 1.128$$

Note that the equations above are from TABLE 3 under lines of code. Thus there are 16 modification factor ratios computed, one for each characteristic, for each of the 8 phases. The resulting matrix follows.

	Requirements Review	Design Rating	Development Rating			Support Software
Lines of Code	F _{1,1}	F _{1,2}	F _{1,3}		•	F _{1,8}
% Memory Fill	F _{2,1}	F _{2,2}	F _{2,3}		•	F _{2,8}
% Timing Fill	F _{3,1}	F _{3,2}	F _{3,3}		•	F _{3,8}
•		•	•		•	
•		•	•		•	
•		•	•		•	
Work Efficiency	F _{16,1}	F _{16,2}	F _{16,3}		•	F _{16,8}

Once these ratios are computed they are positioned according to ascending order within each phase. If j represents the position number (j = 1, 2, 3 ... 16), then a new vector $F_{i,x,j}$ will be formed for each phase x. This is illustrated below:

For example, suppose all of the modification factor ratios for requirements review are computed. The vector would be rearranged in ascending order. This is illustrated below.

		Computed Modificat	tion	Rearranged Modification	
<u>i</u>	Characteristic	Factor Ratios	_ <u>i</u>	Factor Ratios	j
1	Lines of Code	1.536	15	.716	1
2	% Memory Fill	1.000	8	.781	2
3	% Timing Fill	.976	9	.816	3
4	% Work Contractor	1.237	16	.875	4
5	Year of Support	.901	5	.901	5
6	No. Fielded Systems	.978	12	.910	6
7	Change Efficiency	1.372	3	.976	7
8	Language	.781	6	.978	8
9	Dev V&V Rating	.816	13	.996	9
10	Program Design Ratin	g 1.213	2	1.000	10
11	Implementation Ratin	g 1.210	.11	1.210	11
12	Init Documentation	.910	10	1.213	12
13	Type of Aircraft	.996	4	1.237	13
14	Complexity	2.138	7	1.372	14
15	Rate of Change	.716	1	1.536	15
16	Work Efficiency	.875	14	2.138	16

The functions $P_X(H)$ and $P_X(L)$ can now be computed from the resulting vector. The formulas for $P_X(H)$ and $P_X(L)$ are shown below:

$$P_{x}(H) = \int_{j}^{S} \frac{1}{2} ((F_{i,x,j} - 1)(W_{j}) + 1)$$
 (3)

$$P_{x}(L) = \int_{j}^{T} \frac{1}{[F_{j,x,j} - 1)(W_{j}) + 1}$$
 (4)

In the two equations above, \mathbf{W}_{j} is a vector representing various weights applied to the separate impacts of each characteristic. Since the independent impacts of each of the 16 system characteristics can be expected to interact with one another, an additional smoothing algorithm is necessary. This additional smoothing algorithm reduces the compounding effect of two or more factors which affect costs in the same direction.

It should be noted that the effect of incorporating the weighting factors materially affects cost projections only under certain conditions. When two or more characteristic values change such that the separate cost impacts are considerable and in the same direction, the weighting factors will tend to reduce the overall impact on the cost projections. In other words, the combined effect of changing characteristic values will be less than if the individual effects are treated separately and simply added to one another.

The values for W are determined judgmentally based on actual data and expert intuition. The actual values are shown below:

i	Wj
1	1.0
2	.667
3	.50
4	.40
5	.30
6	.20
7	.10
8	.05

S and T in Equations (3) and (4), respectively, are values of j. S represents the number of modification factor ratios that is greater than unity and is constrained to be 8 or less. T is the number of ratios less than unity and is also constrained to be 8 or less. Thus, if more than eight modification factors tend to change costs in the same direction, only the eight with the greatest individual impacts will be included in the computations. The others will be ignored.

To illustrate, the computations of $P_{\chi}(L)$ and $P_{\chi}(H)$ are shown below for the example previously begun.

$$P_{1}(H) = \int_{J}^{6} \prod_{i=1}^{2} ((F_{1,i,j} - 1)(W_{j}) + 1)$$

$$P_{1}(H) = 2.138 \cdot ((1.536-1)(.667)+1) \cdot ((1.372-1)(.50)+1) \cdot ((1.237-1)(.40)+1)$$

$$\cdot ((1.213-1)(.30)-1) \cdot ((1.210-1)(.20)-1)$$

$$P_{1}(H) = 4.1777$$

A PROPERTY OF THE PARTY OF THE

$$P_1(L) = j^{\frac{8}{11}} \frac{1}{(\frac{1}{F_{1,j,j}} - 1)(w_j) + 1}$$

$$P_1(L) = .716 \cdot \frac{1}{(\frac{1}{.781} - 1)(.667) + 1} \cdot \frac{1}{(\frac{1}{.816} - 1)(.50) + 1}$$

•
$$\frac{1}{(\frac{1}{.875} - 1) (.40) + 1}$$
 • $\frac{1}{(\frac{1}{.901} - 1) (.30) + 1}$ • $\frac{1}{(\frac{1}{.910} - 1) (.20) + 1)}$

•
$$\frac{1}{(\frac{1}{.976} - 1)(.10) + 1}$$
 • $\frac{1}{(\frac{1}{.996} - 1)(.05) + 1}$

$$P_1(L) = .4855$$

Thus, in this example the overall impact on requirements review manmonths caused by changes in characteristic values between the representative and historical system is:

$$P_1(L) \cdot P_1(H) = .4855 \cdot 4.1777$$

$$P_1(L) \cdot P_1(H) = 2.0283$$

That is, due to changes in the characteristics between the historical and representative systems, the number of manmonths required for requirements review can be expected to be more than double in this example.

Once the direct labor costs are estimated, indirect labor, direct support equipment, and general support equipment costs can be estimated. This is accomplished by applying the normalization factors and the relationships shown in FIGURE 11. APPENDIX I provides the specific computations.

A representative baseline is derived from each of the seven historical baselines. The computations are based on the changes in characteristic values between the representative and historical systems, using the modification factors and the algorithm described above. The results from this analysis are provided in APPENDIX J. The representative characteristics which these costs reflect are shown above in TABLE 7.

4.5.3 Cost Projections

Once the representative baseline systems are derived, the model is ready to project cost estimates given a new set of characteristics. This set is to be offered by the individual desiring to estimate future costs for various possible system configurations. With this information, the user will be able to reliably compare the costs for the many configuration options which exist during the conceptual phase.

The key to this portion of the algorithm is the set of new characteristic values. As these values are altered from the representative values, the modification factors will be used in precisely the same way as before. Only this time, the representative system characteristics and costs will be the starting point. Applying the modifications as before, direct labor costs are estimated by using the following formula:

FIGURE 11 ESTIMATION OF OTHER COST SEGMENTS

= F (HARDWARE COST)

- Property of a

$$L = \chi \stackrel{8}{=} 1 \frac{R_x \cdot S_p}{S_R} \cdot P_x(H) \cdot P_x(L)$$

R_X = Annual direct labor cost for phase x for the
 representative system

S_p = Cost/manmomth for the derived skill level of the
 proposed system

 S_R = Cost/manmonth for the skill level of the representative system

 $P_{x}(H)$ = Function of modification factors whose overall effect is to increase costs for phase x

 $P_x(L)$ = Function of modification factors whose overall effect is to decrease costs for phase x

Another way of viewing this equation is provided in FIGURE 12. In this equation, the functions $P_X(H)$ and $P_X(L)$ are computed the same way as for the representative baseline costs, except that the modification factors are applied to the representative costs rather than the historical costs. In the equation, R_X/S_R is the number of representative manmonths. Thus, multiplying by $P_X(H)$ and $P_X(L)$ results in the number of manmonths required for the proposed system. Multiplying again by S_p converts the numbers of manmonths to a cost figure.

If is assumed as before that $F_{i,x}$ is defined to be the relative impact on manmonths in phase x caused by modifying system characteristic i, then $F_{i,x}$ is computed as follows:

- PROPERTY SALES

FIGURE 12 COMPUTATION OF LABOR COSTS FOR THE PROPOSED SYSTEM

SUPPORT SOFTWARE (8)	R ₈ /S _R	Sp	P ₈ (L) × P ₈ (H)
TOTAL			

$$F_{i,x} = (C_{i,x}/A_{i,x})$$

where $C_{i,X}$ = The value for each modification factor i for phase x using the characteristics of the proposed system.

A_{i,x} = The value for each modification factor i for phase x using the characteristics of the representative system.

Substituting $C_{i,x}$ for $A_{i,x}$ and $A_{i,x}$ for $B_{i,x}$, $P_X(H)$ and $P_X(L)$ are computed in precisely the same fashion as described in the previous section.

Finally, the labor costs are computed for each of the eight work phases and summed. The total, L in the equation, represents the total annual cost for direct labor. In order to breakdown this total into the eight phases, SYSCON determined that a general methodology would be superior to simply accepting the previously computed subtotals. The reason for this is twofold; first, the historical breakdown of labor costs by phase from which the projections are based may not be representative of a typical system. Second, because of the purpose for which the ASSCM is designed, a general breakout of labor costs is superior. This allows the cost for two or more proposed systems to be more consistently compared.

As a result, SYSCON chose percentages which, when applied to the labor cost total, could be used to estimate the labor cost by phase. These percentages are derived from the historical data available and are deemed most reasonable for all system types. See TABLE 9. The derivation of these figures is shown in APPENDIX K. Thus, to estimate the costs by phase, the percentages are simply multiplied by the projected direct labor cost total.

For other cost elements within the WBS, the normalization factors are applied in the same fashion as for the representative system. See FIGURE 10 above and APPENDIX I for the methodology.

5 COMPUTERIZATION

The computerization phase first involved reviewing the available software and hardware of the systems on which the ASSCM would be installed. This was done to determine if there were any constraints that could impact the program's design specifications. Initial development of the program was done on SYSCON's HP-3000, and this also was taken into consideration. Using the results of the review, a method of automating the model algorithm was developed that would satisfy these requirements. This section addresses the computerization procedures taken to design and develop the ASSCM computer program. For a more detailed discussion of the computer program, see the Computer Program Production Specification (Applicable Document No. 12).

5.1 Design

The purpose of the design phase is to develop a modular approach in transferring the model algorithm into a computer program. A three step process is used as a basis for deriving this modularity.

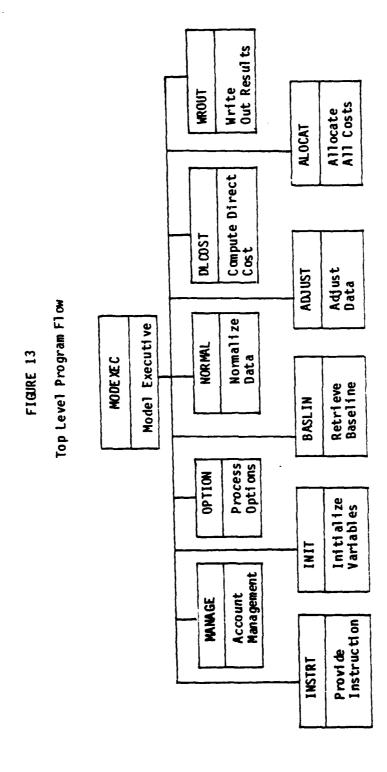

From this point the various processes are further broken down into specific subroutines. Each subroutine is defined on the basis of the task it is designed to perform. This results in eleven specific subroutines which are illustrated in FIGURE 13.

5.1.1 Model Executive (MODEXEC)

The model executive is the first and last subroutine executed and provides overall control for the program. Its main function is to access each of the other 10 subroutines to perform its task.

- Million and the Colon

W. C. W. S.

5.1.2 Instruction Subroutine (INSTRT)

The instruction subroutine allows the operator the option of viewing the instructions. If he chooses to do so, a file containing the instructions on the model and its use is printed out to the user's terminal.

5.1.3 Account Management Subroutine (MANAGE)

The account management subroutine provides the user with the opportunity to create a personal account by supplying his own password. This allows the user to create and save his own input files within this account. Only by providing this password at the beginning of a session can these files be recalled and/or deleted during a future run.

5.1.4 Initialization Subroutine (INIT)

This subroutine allows the user to choose one of the seven baseline systems for which costs are to be projected. The external files containing the appropriate historical data are read in and all necessary variables are initialized based on the system chosen.

5.1.5 User Option Subroutine (OPTION)

The user option subroutine allows the user to supply interactively three types of information. The user may:

- input the appropriate information that describes the proposed embedded computer system software for which software maintenance costs are to be projected
- view and/or modify any of the normalization factors
- choose the desired output format for the ensuing cost projection.

5.1.6 Database Retrieval Subroutine (BASLIN)

This subroutine reads in the data for the historic direct labor mammonths from an external file and initializes the appropriate variables according to the system chosen in the initialization subroutine.

5.1.7 Normalization Subroutine (NORMAL)

The normalization subroutine derives all costs for the historical system using the historic direct labor manmonths and the normalization factors. This results in the historic baseline data for the type of system and application chosen by the user.

5.1.8 Adjustments Subroutine (ADJUST)

This subroutine substitutes the characteric values of the historical and repesentative systems into the modification factors. The modification ratios are then computed and applied to the historic direct labor manmonths by phase to derive the representative baseline direct labor manmonths by phase.

Lastly, all other costs for the representative system are derived using the direct labor manmonths and the normalization factors.

5.1.9 Direct Labor Cost Subroutine (DLCOST)

The direct labor cost subroutine substitutes the characteristic values of the representative and proposed systems into the modification factors. This second set of modification ratios is computed and applied to the representative direct labor manmonths by phase and summed to derive a total direct labor cost for the proposed system.

5.1.10 Cost Allocation Subroutine (ALOCAT)

This subroutine utilizes the total annual direct labor cost projection and cost allocation factors to determine a breakdown of the direct labor costs by phase. In addition, this subroutine derives all other cost elements associated with maintaining the software.

5.1.11 Write Out Subroutine (WROUT)

This subroutine outputs to the user the cost breakdown for the proposed system according to the output formats selected previously by the user.

5.2 Development

The ASSCM computer program was developed over a period of seven months on SYSCON's HP-3000 and VAX 11/780. The program is written in ANSI Standard FORTRAN for interactive use on the ASD Cyber 175 and the Avionics Laboratory VAX 11/780. Two separate programs exist with the only differences being the result of peculiarities present within the respective machines.

5.2.1 Coding

The ASSCM is developed in accordance with the requirements specified in the Software Design Specification (See Applicable Document No. 7). A hierarchical structure is used to provide a cohesive software system which facilitates easy expansion and modification of the model. This also provides for portability of the implemented software between the VAX 11/780 and the Cyber 175 computer systems. The coding of the eleven subroutines and six files was done in four separate stages, each with a well-defined objective. See TABLE 10 for a summary of these four stages.

TO THE OWN TO

NOTE: QUOTES INDICATE EXTERNAL FILES

5.2.2 Integration and Testing

As each stage of coding was completed, top-down integrated testing was performed to ensure conformity with the Software Design Specification and to demonstrate the completion of development milestones. There were four such stages, each successfully completed to insure that the model executed properly.

The first stage of integration consisted of creating an external data base for the four permanent data files. These files contain the historical characteristics, representative characteristics, the normalization factors, and the historic direct labor manmonths by phase. The objective of this first stage was to read in the files and correctly compute the historical baseline of costs for each of the seven systems.

Like the first stage, the second stage did not require any user input. The objective of this stage was to derive the representative baseline data by applying the modification factors to the nistorical baseline. All computations performed by the model were done externally to check for accuracy.

Stage three utilized information provided by the user. Using the characteristic values of a proposed system configuration, the model computed all the projected costs. This is accomplished by applying modification factors to the representative baseline data. The objective here was to confirm that all of the cost information derived was an accurate reflection of the user-inputted characteristics. The results were also compared to computations performed outside the model.

The fourth stage did not involve data manipulation of any kind. The user interface was refined by adding a subroutine to print instructions from an external file. In addition, another subroutine was incorporated into the model to allow the user to create, save, and delete his own input files.

The second of th

6 VALIDATION

6.1 <u>Summary</u>

The development of a cost estimating model cannot be successfully concluded unless there is some way to test how good and how reliable the estimates are. Therefore, it is necessary to evaluate the resulting cost projections to make sure that they are not only plausible, but reasonable as well. Moreover, cost projections must be consistent with the known facts as well as with common sense.

6.2 Methodology

The validation procedure requires data from existing systems that were not used in the development of the ASSCM cost estimating algorithm. This is necessary to insure that the cost projections are derived independently from the existing data to which the projections are to be compared. To accomplish this, SYSCON conducted an exhaustive search to complete its data base as best it could. This resulted in complete cost and characteristic information for two systems and incomplete cost information for an additional system. These are listed below:

System	Type	<u>Application</u>	Cost Data	Characteristic Data
ALQ-155	EW	Integrated System	Complete	Complete
FB-111A	OFP	Navigation, Weapon Delivery	Complete	Complete
ALR-69	EW	Receiver	Incomplete	Complete

In order to facilitate the validation of the ASSCM it is necessary to compare actual costs with those projected by the model. To accomplish this, SYSCON inputted the descriptive characteristics for the three systems listed

above and allowed the model to project the annual software maintenance costs for fiscal year 1981. If the discrepancies between the actual and estimated costs are small or can be reasonably explained, then one can conclude that the model is valid.

By making these comparisons, SYSCON obtained encouraging results. A segment by segment comparison indicated few major discrepancies. Where significant discrepancies did exist, plausible explanations concerning the historic data were readily apparent.

6.3 Validation Results

A summary of the model's projections versus the actual costs is shown below for the major cost segments.

	Ac	tual Cost		Pr	edicted Co	et	P	ercent De	viation
System	Total	Labor	Support	Total	Labor	Support	Total	Labor	Support
ALQ-155	1,862,302	200,509	1,661,793	2,012,825	147,228	1,865,597	+8.1	-26.6	+12.3
FB-111A	8,870,723	280,968	8,589,755	9, 104, 983	368,501	8,736,482	+2.6	+31.2	+1.7
ALR-69	?	7	2,754,286	2,686,117	313,268	2,372,849	7	7	+16.1

As discussed in the Validation Report (Applicable Document No. 13), all of the major differences between actual and estimated costs are explained. These explanations are summarized in FIGURE 14.

It should be pointed out that two important changes were incorporated into two modification factors and one normalization factor directly as a result of the validation comparisons. That is, the validation process uncovered previous errors that became readily apparent only after a comparison of the actual and projected costs was made. This led to the reduction of impact on costs for low percentages of percent memory fill and percent timing

- No Carte Contract

FIGURE 14

REASONS FOR MAJOR DISCREPANCIES BETWEEN HISTORIC AND PROJECTED COSTS

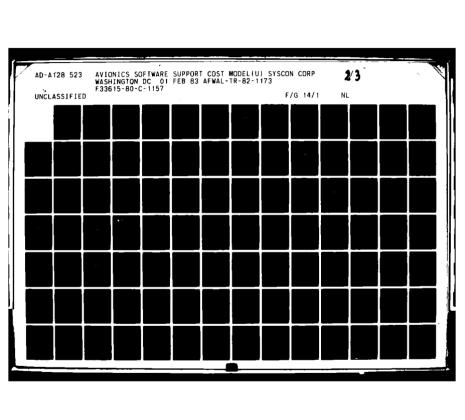

System	Cost Segment	Explanation
ALQ-155	Direct Labor (Support Software)	Actual costs exhibited an abnormally high proportion of time to maintain the support software in this second block change
	Support Equipment (Test Aircraft/Time)	No actual costs were expended for this cost segment. This is highly irregular
FB-111A	Direct Labor (Development, Integration)	Model may overstate costs when percentage of work performed by contractors is high; implementation structure rating may be in error
	Support Equipment (Test Aircraft/Time)	Actual costs appear to be low when compared to costs experienced during previous block changes
ALR-69	Support Equipment (Test Aircraft/Time)	Estimate is computed directly from the direct labor T&E estimate which was high. Estimates assume all work performed organically when at least two phases of work were performed by contractors. Model is not designed to handle this situation
	Support Equipmen' (Reproduction)	Actual work was performed by contractors. Model is not designed to handle this situation.

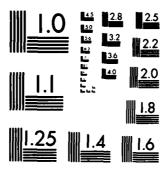

Same has the state of the

A STATE OF THE STA

fill (See footnote 1 in TABLE 3) and the addition of a time-dependent K for the PROM's medium factor (see footnote 1 in TABLE 1-D).

In summary, SYSCON concludes that to the extent possible, the ASSCM has snown that it provides reasonable, accurate cost projections for existing systems. Part of this success is due to the support costs being known. During the conceptual phase, where these costs are not known the model may not be expected to be as accurate. SYSCON believes though, and has demonstrated, that the ASSCM can be used with confidence to project and support cost estimates for maintaining the software on proposed avionics systems in the future.

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

7 INSTALLATION AND TRAINING

7.1 Installation

The ASSCM computer program was successfully installed on the VAX 11/780 at Wright-Patterson Air Force Base. This task was simplified since final development of the model was completed on SYSCON's VAX 11/780. Once the program was compiled and executing correctly on the VAX, a separate tape was made for installation on the ASD Cyber 175. Once installed, some modifications were made to the program source code to allow the ASSCM to be compiled and executed correctly on the Cyber 175 system. Thus, one version is currently being maintained for both of the Air Force's systems. For a summary of the differences between the two versions, refer to the Computer Program Product Specification. (Applicable Document No. 12)

7.2 Training

A one-day training course was given at Wright-Patterson Air Force Base for all necessary Air Force and DOD personnel. At that time an oral presentation was given and the training materials and User's Manual were delivered. The training course covered model description, user interface, model algorithm, and internal computations performed by the ASSCM computer program.

8 FUTURE CONSIDERATIONS

This section details four areas where SYSCON feels that additional effort may be expended by the Air Force to expand or enhance the capabilities of the ASSCM. The four suggested areas are listed below.

- Development of Data Collection Techniques
- Collection of Additional Data
- Addition of New Systems and System Applications to the Model
- Modification of the Model To Support Other Requirements
 The first two areas deal with the collection of cost data to support the model. The last two are concerned with adding capabilities to the model to support additional Air Force requirements. Each of these areas are discussed in the following paragraphs.

8.1 Development of Data Collection Techniques

The first year of the ASSCM developent effort centered around the design of the ASSCM algorithm and the collection of cost data from the ALC's to support the algorithm. It was determined during the initial data collection trip that little data was available. When data was available, it was frequently poorly organized and not readily useable. (See APPENDIX A.)

SYSCON suggests that the Air Force support an effort to develop a cost and tracking methodology which may be applied across all ALC's. This methodology must include but not be limited to:

- identification of all data to be collected
- identification of sources for this data
- providing standard reporting and data collection forms
- identification of filing requirements
- identification of audit requirements to insure timely and accurate data collection.

- Fire Charles

This methodology is just a first step to insure pertinent, reliable, and accurate information for future model developments and accurate cost tracking. The time spent by the ALC personnel to collect, correlate and report this data will be more than offset by their increased visibility into the costs associated with the software support area.

8.2 Collection of Additional Data

The model developed and implemented by SYSCON is a viable means to estimate costs associated with avionics software support. As with any model, nowever, the accuracy of the model is only as good as the data which supports the model. SYSCON has endeavored to make the model flexible and maintainable. To meet this end, all cost data used to support the model can be easily updated to allow for the use of newer, more accurate cost information.

SYSCON feels that the Air Force should review the costs associated with the software support area at least every two years and incorporate any additional information into the model. This will insure that cost projections estimated by the model will be based on the most current information.

This effort may be best organized if it is tied with the development of data collection techniques discussed in the previous section.

8.3 Addition of New Systems and System Applications

The development of the ASSCM, as specificed in the government statement of work, does not address the software support cost associated with Automatic Test Equipment (ATE) and Aircrew Training Devices (ATD). The model, as designed, could easily be updated to estimate costs for these systems as well. Moreover, additional applications of CE, EW, and OFP systems may be

added to increase the capabilities of the model's projections to cover these new areas. The effort in all cases would require data collection, model modification, testing, validation, and documentation.

8.4 Modification of the Model

As with many model developments, the ASSCM is designed to support a specific requirement. The methodology employed, however, is well suited to many applications where the volume of data is inadequate to support traditional cost estimating techniques. The applicability of the model methodology must be assessed on a case by case basis. The unique algorithm developed for the ASSCM is appropriate when the need arises to project costs and very little data exists to support the projections. The algorithm utilizes the historic data available plus the judgment of cost experts. Moreover, the methodology breaks down each individual cost estimate to a much more manageable degree and then sums up all of the pieces to arrive at a final estimate.

The ASSCM, as developed by SYSCON, might also support additional requirements in the software support area. Requirements of other labs and divisions within ASD, as well as requirements of AFLC, might be addressed through minor changes in the model's output.

APPENDICES

APPENDIX A

DATA COLLECTIONS PROBLEMS

Direct Labor

Total manhours required to complete a block change appear to be available from Form 75. This is the only source of documentation. It will be difficult, however, to match manhours with the cost per manhour for the following reasons: 1) people are not necessarily dedicated to one change block or system; 2) contractors perform part of the work for which manhours may or may not be available; 3) new hires and resignations are common causing turnover; 4) the nature of the work causes training to be long and tedious, resulting in a high variation of productivity; 5) Form 75 data represent only an estimate of hours; 6) the cost per manhour or GS grade of a worker does not necessarily indicate the degree of productivity; and 7) manhours are not necessarily broken out by task as desired according to the WBS.

It should also be noted that the number of manhours and the cost per manhour reported might reflect the availability rather than the requirement for people. This is because the work involved is exceedingly specialized, and manpower needs cannot be met under optimal conditions.

In the opinion of several Air Force personnel, manhours by task could be obtained along with their cost from available Government records (other than Form 75) and interviews. The effort necessary to complete this research in order to recreate the manpower expended would be tedious, perhaps taking as long as a manmonth for each system. Such an attempt was not made during the data collection trip.

Indirect Labor

Indirect labor costs include supervision and administration. These hours are not normally broken out by system so no data is available. It does seem possible, however, that an estimate could be made based on the amount of direct labor spent on a particular block change. Perhaps only a percentage of the direct labor cost is all that is necessary. In any event, the collection of actual manhours and costs for each system does not seem possible given a reasonable time frame to collect this data.

Direct Support Equipment

Direct support equipment varies tremendously among systems. Thus, the estimation of costs for this equipment is difficult, especially because of the lack of relationship between specific cost drivers and costs.

THE RESERVE TO

The collection of meaningful equipment cost information is hindered for the following reasons: 1) the equipment cost is included as part of the development contract and is thus difficult to obtain; 2) equipment may be leased, with no purchase price available; 3) the equipment might be outdated (because of the technological advances over the past 5 years) or might be much cheaper if purchased today; 4) the date on which equipment was purchased is not always available; and 5) the purchasing of equipment is decentralized.

There is no single source to obtain cost information from. Thus, obtaining the cost of all direct equipment will require significant time and resources to exhaust all data sources for each system.

General Support Equipment

Cost information on shared support euqipment is not available in a useable form. The sources for any of this information are decentralized and, of course, it is difficult to break out the costs according to system. Ideally, one would attribute total costs of a piece of equipment based on some measurement of usage. In reality, this is almost impossible to do without being subjective. Even the total costs which are to be divided up among the various systems would be difficult to obtain without significant effort for each piece of information.

Conclusion

In summary it appears to be a very costly and time consuming effort to collect all of the relevant cost information necessary to support avionics software changes. The job is not impossible. It requires a person to check out all data sources and spend a great deal of time with the various supervisors in order to document the evolution of each system. It does not appear to be practical for the Air Force to pursue such a data collection effort because 1) there is some risk that the quantification of cost estimating relationships might not be possible even if sufficient data is collected and 2) the cost of conducting such a study is too great in comparison to the benefits of obtaining an objective cost estimate (which may or may not be better than a subjective one).

WANTED BY STATE OF THE PARTY OF

APPENDIX B

AVIONICS SUPPORT COST ESTIMATION QUESTIONNAIRE (PHASE I)

This questionnaire is to be filled out by knowledgeable people in the field of avionics software support. Because of your background and experience, you have been chosen to help in this study to predict software support costs. Please answer all questions in which you feel you are qualified to provide the necessary information or express an opinion. If you have no experience in the area being questioned, do not answer the question. However, do not be modest—your opinions are important and there are few people in addition to yourselves that are more qualified to answer this questionnaire.

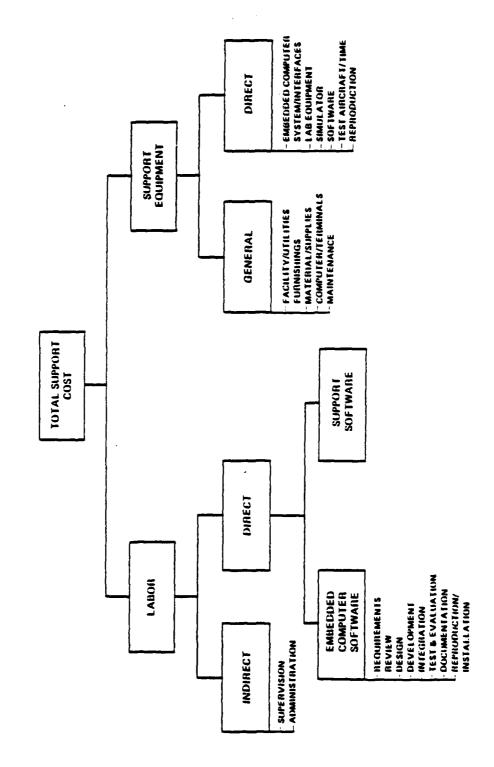

SYSCON has defined avionics software support costs into four categories: direct and indirect labor costs and direct and general support equipment costs. These costs are further broken down according to the work breakdown structure shown on the next page. Please keep in mind the kind of cost referred to by a question as you respond to it.

There are two phases to this questionnaire. This first portion consists of two sections. Section I asks for specific technical and direct labor information about the avionics system to which you are directly assigned. The second section, Section II, concerns various subjects that are less technical in nature but are important for predicting costs other than direct labor necessary to support avionics embedded computer systems.

Sections III and IV will be distributed to you at a later date. They will elicit your expert opinions about how hypothetical changes in certain factors affect direct labor costs.

Please read the instructions at the beginning of each section carefully and answer all questions that you can. Discussion of a particular question with another person or several people is permitted. However, it is important that answers be as reliable as possible. In some cases where information has already been provided to SYSCON, the answers will be filled in. In this circumstance, you are asked merely to confirm your previously supplied data.

AVIONICS SUPPORT COST ESTIMATION QUESTIONNAIRE (PHASE II)

This questionnaire is to be filled out by knowledgeable people in the field of avionics software support. Because of your background and experience, you have been chosen to help in this study to predict software support costs. Please answer all questions in which you feel you are qualified to provide the necessary information or express an opinion. If you have no experience in the area being questioned, do not answer the question. However, do not be modest—your opinions are important and there are few people in addition to yourselves that are more qualified to answer this questionnaire.

SYSCON has defined avionics software support costs into four categories: direct and indirect labor costs and direct and general support equipment costs. These costs are further broken down according to the work breakdown structure shown on the next page. The most important cost component is direct labor expended in supporting the embedded computer system. All of the questions in this second phase of the questionnaire relate to the estimation of direct labor costs. Section III (the first section of Phase II) concerns the impact of certain factors on direct labor costs under several hypothetical conditions. These questions are designed to elicit your best judgment. The final part, Section IV, asks you to define the technical parameters and attributes of an "average" system.

Please read the instructions at the beginning of each section carefully and answer all questions that you can. If you do not understand the question, ask for clarification. You will be given a chance to change your answers at a later date when the results from all respondents are tabulated and made known to you.

- Simulation .

SECTION III

The following questions ask for your expert opinion on how a change in one factor impacts on avionics software direct labor costs. When answering these questions assume that all other factors remain unchanged. Also, you may assume (unless otherwise specified) that the following characteristics about a general system apply:

Lines of code: 16K Program design: unstructured

Language: assembly Program implementation: unstructured

Z memory fill: 75% Initial documentation: incomplete and

outdated

% timing fill: 75% Year of Support: 3

Work performed: totally organic Application: Navigation

Development V&V: Performed by Type of Aircraft: Fighter

developer

Complexity rating $\frac{1}{2}$: 3 Number of fielded systems: 600

Rate of change $\frac{1}{2}$: 3 Skill Level Mix $\frac{1}{2}$: 3

Change Efficiency $\frac{2}{}$: 50%

With these characteristics in mind, please answer the following questions about the <u>relative</u> impact on the number of required manhours within each phase of direct labor. For example, if the question asks you to focus on the impact of changing the program size from 16K to 24K, all other factors being equal, you might expect software support direct labor manhours for requirements review to remain the same whereas the labor manhours for the design phase would increase by 15Z. That being the case, you would fill in 1.00 in the requirements review block under 24K, and 1.15 in the design block under 24K.

If you feel a situation is not reasonably possible, fill in NA for not applicable.

 $\frac{1}{2}$ See page 112 for the definition of each rating.

2/ See page 121 for the definition.

APPENDIX G

APPENDIX G

1054 31 ST STREET, N.W. WASHINGTON, D.C. 20007 PHONE: (202) 342-4000 TWX: (710) 822-0103

You may recall that earlier this year, Rich Bentley and I visited your Air Logistics Center in order to collect information concerning the costs of maintaining embedded computer software. SYSCON Corporation is under contract from the Avionics Lab at Wright-Patterson to develop a computer model to estimate these costs during the conceptual stage of avionics system design.

You were chosen to take part in Phase II of our two-phase questionnaire. Because of the subjective nature of the information requested, we feel the reliability of the data you provided would be enhanced if you had one final opportunity to review your answers. This method for data collection, known as the Delphi Technique, requests you to compare your answers to the averages computed from the answers provided by all of the respondents. You thus have one last opportunity to change any or all of your answers.

The purpose of this final review is to allow you to see how your peers interpreted the same questions. We have enclosed a computer printout of each question and your previous answers. Below each of your answers is the average as computed from all 39 respondents. In this way we hope we have made it simple for you to compare your previous answers to the averages. Please also keep in mind that some questions were misinterpreted. You should note this when comparing your answers to the averages.

In computing averages we have omitted answers left blank. In addition, we set a limit of 10 to reduce the impact of any one answer on the computed averages. Thus, if a respondent felt that costs would increase by a factor of 10 or more, an answer of 10 was substituted. We would greatly appreciate your help one last time so that we can finalize our mathematical algorithms. If you feel any changes are in order or wish to fill in answers you previously left blank, simply cross out your old answer and insert the new one in its place. Keep in mind that you do not have to change your answers. It will be easier for us if you work with a red pencil or pen. Also, if your answer and the group average are both shown to be 1.00, no changes are necessary. You may recall that these were present only to establish a point of reference and are not subject to change.

This review should take you no more than half an hour. When you are finished, please return the questionnaire in the self-addressed, stamped envelop enclosed for this purpose by 12 December 1981. If there are any questions, please feel free to call me at 800-424-8503.

Thank you very much for your help and support.

Sincerely,

John Murray

AVIONICS SUPPORT COST ESTIMATION QUESTIONNAIRE (PHASE II)

This questionnaire is to be filled out by knowledgeable people in the field of avionics software support. Because of your background and experience, you have been chosen to help in this study to predict software support costs. Please answer all questions in which you feel you are qualified to provide the necessary information or express an opinion. If you have no experience in the area being questioned, do not answer the question. However, do not be modest—your opinions are important and there are few people in addition to yourselves that are more qualified to answer this questionnaire.

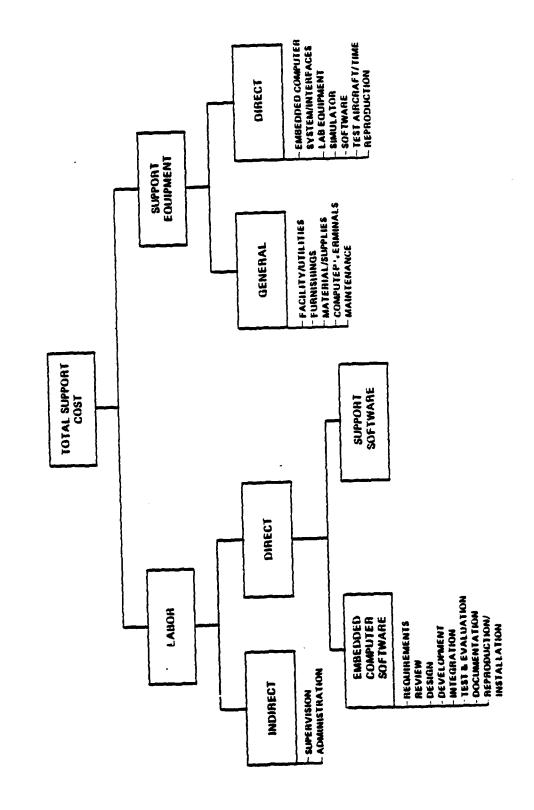

SYSCON has defined avionics software support costs into four categories: direct and indirect labor costs and direct and general support equipment costs. These costs are further broken down according to the work breakdown structure shown on the next page. The most important cost component is direct labor expended in supporting the embedded computer system. All of the questions in this second phase of the questionnaire relate to the estimation of direct labor costs. Section III (the first section of Phase II) concerns the impact of certain factors on direct labor costs under several hypothetical conditions. These questions are designed to elicit your best judgment. The final part, Section IV, asks you to define the technical parameters and attributes of an "average" system.

Please read the instructions at the beginning of each section carefully and answer all questions that you can. If you do not understand the question, ask for clarification. You will be given a chance to change your answers at a later date when the results from all respondents are tabulated and made known to you.

Phone:	
Ti =10.	

SECTION III

The following questions ask for your expert opinion on how a change in one factor impacts on avionics software direct labor costs. When answering these questions assume that all other factors remain unchanged. Also, you may assume (unless otherwise specified) that the following characteristics about a general system apply:

Lines of code: 16K Program design: unstructured

Language: assembly Program implementation: unstructured

% memory fill: 75% Initial documentation: incomplete and

outdated

I timing fill: 75% Year of Support: 3

Work performed: totally organic Application: Navigation

Development V&V: Performed by Type of Aircraft: Fighter

developer

Complexity rating $\frac{1}{2}$: 3 Number of fielded systems: 600

Rate of change $\frac{1}{2}$: 3 Skill Level Mix $\frac{1}{2}$: 3

Change Efficiency $\frac{2}{2}$: 50%

With these characteristics in mind, please answer the following questions about the relative impact on the number of required manhours within each phase of direct labor. For example, if the question asks you to focus on the impact of changing the program size from 16K to 24K, all other factors being equal, you might expect software support direct labor manhours for requirements review to remain the same whereas the labor manhours for the design phase would increase by 15%. That being the case, you would fill in 1.00 in the requirements review block under 24K, and 1.15 in the design block under 24K.

If you feel a situation is not reasonably possible, fill in NA for not applicable.

 $\frac{1}{2}$ See page 134 for the definition of each rating.

 $\frac{2}{2}$ See page 142 for the definition.

4. M. S. W.

DEFINITIONS

Complexity Definitions:

- (1) Easy to read and follow code, many similar applications.
- (2) Time required to gain familiarity with code, many similar applications.
- (3) Time required to gain familiarity with code, few similar applications, approaching state-of-the-art.
- (4) Extremely difficult to understand code, few similar applications.
- (5) Extremely difficult to understand code, unique application, beyond the state-of-the-art.

Rate of Change Definitions:

- (1) Stable code, changes required very infrequently, minimal staffing required.
- (2) Infrequent changes required on a periodic basis, staffing assigned on a part-time basis.
- (3) Changes required on a periodic basis, staffing requirements fairly constant.
- (4) Frequent changes, changes require immediate attention,
 full-time staff required plus additional personnel for pertubations.
- (5) Changes required continuously, full-time staff plus additional personnel have difficulty keeping up with user requirements.

Skill Level Mix Definitions:

- (1) Predominantly inexperienced, junior personnel unfamiliar with the software system.
- (2) Variety of personnel with a limited working knowledge of the software system.
- (3) Typical personnel with some experience with the software system, mix of junior and senior personnel.
- (4) Predominantly senior personnel with a good working knowledge of the software system.
- (5) Highly experienced, senior personnel with an in-depth knowledge of the software system.

1. RELATIVE IMPACT ON MANHUURS FROM A CHANGE IN THE NUMBER OF LINES OF CODE. ASSUME THAT THE REQUIREMENTS OF THE VARIOUS PROGRAM SIZES REFLECT THEIR RELATIVE COMPLEXITY. THUS, IT IS OBVIOUS THAT A 32K PROGRAM IS MUCH MOKE COMPLEX THAN A 4K PROGRAM.

COST (1981s)	3041000.	3959000.	7000000.
EXPECTED SYSTEM LIFE	20	20	20
*****	*********		
ANNUAL EQUIPMENT COST	152050.	197950.	350000.

TEST AIRCRAFT/TIME

ANNUAL TEE MANMONTHS X 144 = ANNUAL TEE MANHOURS 2.36 X 144 = 339.50

TEST AIRCRAFT HOURS X COST/HOUR = ANNUAL AIRCRAFT/TIME COST 11.88 X 6000. = 71296.

PEPRODUCTION

NUMBER OF FIELDED SYSTEMS X MED REP-FACT X COST/REPRO = PEPRODUCTION COST 100 X 25.000 X 17.00 = 42500.

REPRODUCTION COST X 12 / BLOCK CHANGE LENGTH = ANNUAL REPRODUCTION COST 42500. X 12 / 12 = 42500.

DIFECT SUPPORT EQUIPMENT COSTS

DIRECT HARDWARE COST	152050.
DIRECT SOFTWARE COST	197950.
AIRCRAFT/TIME COST	71296.
+ PEPRODUCTION COST	42500.
DIRECT SUPPORT FOUTPERENT COST	447704

REPRESENTATIVE SYSTEM
YEAR 1961

PEOPLE REGUIRED

PEQUIRED ANNUAL ON-SITE MANMONTHS / 12 = NO. OF DIPECT SUPPORT PEOPLE 31.32 / 12 = 3

ANNUAL SUPERVISION MANMONTHS / 12 = NO. OF SUPERVISORS
4.07 / 12 = 1

ANNUAL ADMINISTRATIVE MANMONTHS / 12 = NO. OF ADMINISTRIRS
4.07 / 12 = 1

NC. OF DIRECT SUPPORT PEOPLE 3
NO. OF SUPERVISORS 1
+ NO. OF ADMINISTRATORS 1

FACILITY

NO. OF PEOPLE

DIRECT SUPPORT PEOPLE X REQ. TECHNICAL SPACE/PERSON = REQ. #ORKING SPACE 3 X 275. = 825.00

(SUPERVSRS + ADMNSTRTRS) X REQ. SUPERVISORY SPACE/PERSON = ADDITIONAL SPACE

(1 + 1) X 130. = 260.00

REQUIRED WORKING SPACE + ADDITIONAL SPACE = TOTAL SPACE #25.00 + 260.00 = 1085.00

TOTAL SPACE X COST/SQUARE FOOT = FACILITY COST 1085.00 X 136.00 = 147560.

FACILITY COST / EXPECTED SYSTEM LIFE = ANNUAL FACILITY COST 147560. / 20 = 7378.

UTILITIES

TOTAL SPACE X COST/SQUARE FOOT = UTILITY COST 1085.00 X 1.20 = 1302.

(CE) COMHAND AND CONTROL

DERIVATION OF ANNUAL GENERAL SUPPORT EQUIPMENT COSTS (1981s)

REPRESENTATIVE SYSTEM

YEAR 1981

FURNISHINGS

TOTAL PERSONS X INITIAL COST/PERSON = INITIAL FURNISHINGS COST
5 X 680. = 3400.

INITIAL FUNRNISHINGS COST / EXPECTED SYSTEM LIFE = ANNUAL FURNISHINGS COST 3400. / 20 = 170.

MATERIALS AND SUPPLIES

TOTAL PEPSONS X COST/PERSON = MATERIALS & SUPPLIES COST 5 X 700. = 3500.

COMPUTERS/TERMINALS

HO. PIRECT SUPPORT PEOPLE X INITIAL COST/PERSON = INITIAL COMP TERM COST
3 X 20000. = 60000.

INITIAL COMP TERM COST / EXPECTED SYSTEM LIFE = ANNUAL COMP TERM COST 60000. / 20 = 3000.

HAPCWAPE MAINTENANCE

FARDWARE COST (1981s) X MAINTENANCE RATIO = ANNUAL HARDWARE MAINTENANCE COS 3041000. X 0.10 = 304100.

GENEPAL SUPPORT EQUIPMENT COST

	FACILITY COST	7378.
	UTILITY COST	1302.
	FUPNISHINGS COST	170.
	MATERIALS & SUPPLIES COST	3500.
	CCMPUTERS/TERMINALS COST	3000.
١	HAPDWAPE MAINTENANCE COST	304100.
	GENERAL SUPPORT EQUIPMENT COST	319450.
