THE MINMAX THEOREM FOR U.S.C.-L.S.C. PAYOFF FUNCTIONS*

by

Jean-François Mertens**

1. Introduction

Our aim is to get a "general minimax theorem" whose assumptions and conclusions are phrased only in terms of the data of the problem, i.e. the pair of pure strategy sets S and T and the payoff function on S × T. For the assumptions, this means that we want to avoid any assumption of the type "there exists a topology (or a measurable structure) on S and (or) T such that..." For the conclusions, we are led to require that players have ε-optimal strategies with finite support, both because those are the easiest to describe in intrinsic terms, and because in any game where the value would not exist in strategies with finite support, all known general minmax theorems implicitly select as "value" either the sup inf or the inf sup by in effect restricting either player I or player II arbitrarily to strategies with finite support - so that the resulting "value" is completely arbitrary and misleading.

Those points are discussed in more detail in Section 3, after having proved a first theorem in Section 2.

---

2.   A First Theorem

<u>Minmax Theorem</u>: A two person zero sum game with compact strategy
spaces has a value and each player has ε-optimal strategies with finite
support if each player's payoff is, for any fixed strategy of his
opponent, an uppersemicontinuous (u.s.c.) function of his strategy, and
is bounded either from above or from below.

[In this Section 2, "compact" means compact and Hausdorff.]

<u>Proof</u>: Let f denote the first player's payoff function, S his
strategy space, and T his opponent's strategy space. For any pair of
mixed strategies σ and τ, we will denote by $f(\sigma,\tau)$ the expectation
of f under the corresponding product measure, whenever this expectation
is unambiguously defined (via Fubini's theorem).

A function f on a compact space K is u.s.c. if and only if
f: $K \rightarrow R \cup \{-\infty\}$ and $\forall \alpha \in R$, $\{x \mid f(x) \geq \alpha\}$ is closed, or equivalently,
if and only if f is the pointwise limit of a decreasing net of continuous
real valued functions on K. f is lowersemicontinous (l.s.c.) if
and only if -f is u.s.c.. Remark that if f is l.s.c., then f is
bounded from below, so each player guarantees himself a finite payoff
with any pure strategy.

The proof starts by proving particular cases of the statement;
the first of them is standard and is just recalled for the reader's
convenience.

(A) Case where S or T -say T- is finite (Von Neumann).

Proof: Let $T = \{t_1,\ldots,t_n\}$ and let C denote the closed convex set $\{x \in \underset{\sim}{R}^n \mid \exists\, \sigma$ probability on S (with # Supp(σ) $\leq$ n (Caratheodory)): $\forall i,\ \int f(s,t_i)d\sigma(s) \geq x_i\}$. Let $v = \underset{x \in C}{\max} \underset{i}{\min}\ x_i$; then $\forall\, \varepsilon > 0$, $[C - (v+\varepsilon)] \cap R_+^n = \phi$, so that for a separating hyperplane $(\lambda_1,\ldots,\lambda_n)$ we have $\underset{y \in C-(v+\varepsilon)}{\sup}\ <\lambda,y> < 0$, $\lambda_i \geq 0$, and also by normalizing $\sum \lambda_i = 1$: player II has a strategy λ such that $\forall\, x \in C,\ <\lambda,x> \leq v + \varepsilon$. When $\varepsilon \to 0$, we get by compactness a strategy λ: $<\lambda,x> \leq v$, $\forall\, x \in C$.

(B) Corollary: Let T be an arbitrary set, f(s,t) u.s.c. on S for each $t \in T$. Then $\underset{\sigma}{\max} \underset{\tau}{\inf}\ f(\sigma,\tau) = \underset{\tau}{\inf} \underset{\sigma}{\max}\ f(\sigma,\tau)$, where σ ranges over all regular Borel probabilities on S and τ over all probabilities with finite support on T.

Proof: For any finite subset $\tilde{T}$ of T, let $\sum_{\varepsilon,\tilde{T}}$ denote the set of σ's satisfying $\underset{t \in \tilde{T}}{\inf}\ f(\sigma,t) \geq \underset{\tau}{\inf} \underset{\sigma}{\max}\ f(\sigma,\tau) - \varepsilon$. By (A), the $\sum_{\varepsilon,\tilde{T}}$ form a decreasing net of non-empty compact sets, so have a non-empty intersection. Any σ_0 in the intersection yields $\underset{\tau}{\inf}\ f(\sigma_0,\tau) = \underset{\tau}{\inf} \underset{\sigma}{\max}\ f(\sigma,\tau)$.

(C) Case where one of the strategy spaces -say T- is metrisable.

(i) Claim: f is Borel measurable.

Let $\phi_1,\phi_2,\phi_3,\ldots$ be a dense sequence of continuous functions on T.

Denote by S_i the closed set $\{s \mid \forall\, t \in T,\ f(s,t) \geq \phi_i(t)\}$, and let $\psi_i(s,t) = \phi_i(t)$ for $s \in S_i$, $= -\infty$ otherwise. Obviously ψ_i is Borel measurable, and therefore also $f = \underset{i}{\sup}\ \psi_i$.

(ii) Denote by $\sum$ (resp. $\overline{T}$) the space of regular Borel probabilities on S (resp. T), and by $\sum_f$ (resp. $\overline{T}_f$) the probabilities with finite support.

f being Borel measurable and bounded either from above or from below, $f(\sigma,\tau)$ is well defined on $\sum \times \overline{T}$.

By (B), there exist $\bar{v} \in \underset{\sim}{R}$ and $\sigma_0 \in \sum$ such that

$$f(\sigma_0,t) \geq \bar{v} = \inf_{\tau \in \overline{T}_f} \sup_{\sigma \in \sum_f} f(\sigma,\tau) \qquad \forall\, t \in T$$

and there exist $\underset{\sim}{v} \in \underset{\sim}{R}$ and $\tau_0 \in \overline{T}$ such that

$$f(s,\tau_0) \leq \underline{v} = \sup_{\sigma \in \sum_f} \inf_{\tau \in \overline{T}_f} f(\sigma,\tau) \qquad \forall\, s \in S \quad .$$

On the one hand, one has always $\underline{v} = \sup \inf \leq \inf \sup = \bar{v}$, on the other hand one gets $f(\sigma_0,\tau_0) = \int f(\sigma_0,t)d\tau_0(t) \geq \bar{v} \geq \underline{v} \geq \int f(s,\tau_0)d\sigma_0(s) = f(\sigma_0,\tau_0)$, and thus the desired equality $\underline{v} = \bar{v}$.

(D) General Case

(i) Construction of a countable set of best replies.

Let $\bar{v} = \inf_{\overline{T}_f} \sup_{\sum_f} f(\sigma,\tau)$, and let $\overline{T}_n$ denote those $\tau \in \overline{T}_f$ with # Supp $(\tau) \leq n$. Denote also by F the set of continuous functions ϕ on T for which there exists $s \in S$ such that $f(s,t) \geq \phi(t)\ \forall\, t \in T$: then $\bar{v} \leq \inf_{\tau \in \overline{T}_n} \sup_{\phi \in F} \int \phi\, d\tau$.

$$\forall\, \phi \in F \quad,\quad \text{let } O_{\phi,k,n} = \{\tau \in \overline{T}_n \mid \int \phi\, d\tau > \bar{v} - \frac{1}{k}\} \quad .$$

The $0_{\phi,k,n}$ form, for each fixed k and n, an open covering of the compact space $\overline{T}_n$. Let $\Phi_{k,n}$ denote a finite subset of F such that $\bigcup_{\phi \in \Phi_{k,n}} 0_{\phi,k,n} = \overline{T}_n$.

Then $\Phi = \bigcup_{k,n} \Phi_{k,n}$ is a countable subset of F, such that $\bar{v} = \inf_{\tau \in \overline{T}_f} \sup_{\phi \in \Phi} \int \phi d\tau$.

(ii) Reduction to Case (C).

If ϕ_i enumerates Φ, let $d(t_1,t_2) = \sum_i 2^{-i} |\phi_i(t_1) - \phi_i(t_2)|/\|\phi_i\|$. d defines a metrisable quotient space $\tilde{T}$ of T, such that, if ψ denotes the quotient mapping, any $\phi \in \Phi$ can be written as $g \circ \psi$, for some $g \in C(\tilde{T})$ - where, for some $s \in S$, $(g \circ \psi)(t) \leq f(s,t)$ $\forall t \in T$. Let Ψ denote the set of all $g \in C(\tilde{T})$ having this property.

Define $\tilde{f}$ on $S \times \tilde{T}$ by $\tilde{f}(s,\tilde{t}) = \sup \{g(\tilde{t}) \mid g \in C(\tilde{T}), (g \circ \psi)(.) \leq f(s,.)\}$. Then, from (i), $\bar{v} = \inf_{\tau \in \overline{T}_f} \sup_{\phi \in \Phi} \int \phi d\tau \leq \inf_{\tau \in \overline{T}_f} \sup_{g \in \Psi} \int (g \circ \psi)(t) d\tau(t) \leq \inf_{\tau \in \overline{\tilde{T}}_f} \sup_{s \in S} \int \tilde{f}(s,\tilde{t}) d\tilde{\tau}(\tilde{t})$. Obviously $\tilde{f}$ is l.s.c. on $\tilde{T}$ for each $s \in S$, and is the largest such function satisfying $\tilde{f}(s,\psi(t)) \leq f(s,t)$.

Let $h(s,\tilde{t}) = \inf \{f(s,t) \mid t \in \psi^{-1}(\tilde{t})\}$: if we show that $h(s,\tilde{t})$ is l.s.c. on $\tilde{T}$ for each $s \in S$, it will follow that $\tilde{f} = h$, and therefore that $\tilde{f}$ is also u.s.c. on S for each $\tilde{t} \in \tilde{T}$ - as an infimum of u.s.c. functions.

Since $\tilde{T}$ is metrisable, denote by $\tilde{t}_i$ a sequence converging to $\tilde{t}_\infty$. Choose $t_i \in T$ such that $\psi(t_i) = \tilde{t}_i$ and $f(s,t_i) \leq h(s,\tilde{t}_i) + 1/i$, and let t_∞ be a limit point of t_i: we have $\psi(t_\infty) = \tilde{t}_\infty$, and

$h(s,\tilde{t}_\infty) \leq f(s,t_\infty) \leq \lim_{i\to\infty} \inf f(s,t_i) \leq \lim_{i\to\infty} \inf h(s,\tilde{t}_i)$ - hence the result.

(iii) Conclusion.

$\tilde{f}$ on $S \times \tilde{T}$ satisfies all assumptions of (C), and from (ii) we

have $\tilde{f}(s,\psi(t)) \leq f(s,t)$ and $\bar{v} \leq \inf_{\tau \in \tilde{T}_f} \sup_{s \in S} \int \tilde{f}(s,\tilde{t})d\tilde{\tau}(\tilde{t})$.

From (C), we know therefore that

$$\bar{v} \leq \sup_{\sigma \in \mathcal{S}_f} \inf_{\tilde{t} \in \tilde{T}} \int \tilde{f}(s,\tilde{t})d\sigma(s) \leq \sup_{\sigma \in \mathcal{S}_f} \inf_{t \in T} f(\sigma,t) \quad ,$$

which completes the proof, the reverse inequality being obvious.

3. Comments on the Present Result

(i) The compactness assumption on both sides is really needed, as

the following example due to H. Kuhn shows (private communication through

R.J. Aumann, example originates from Kuhn's "Lecture Notes in Game Theory"

[~1949], unpublished).

Player I picks a number x in $[0,1]$, and player II chooses a

continuous function ψ from $[0,1]$ to itself with $\int \psi(t)dt = 1/2$.

The payoff is $\psi(x)$. Then player I can guarantee $1/2$ by choosing x

uniformly distributed and player II by taking $\psi(t) = 1/2$ ∀t. But for

any strategy of I with finite support, player II can choose an appropriate

ψ that vanishes on the support - so player I cannot guarantee more than

zero using strategies with finite support.

Remark here that if player II's strategy space is endowed with

the uniform topology, we have a compact metric strategy space for player

I, and a complete separable metric for II, and the payoff is uniformly

bounded and a uniformly continuous function of player II's strategy -

in particular it is jointly continuous on S × T: even with much
stronger assumptions everywhere else, just the failure of the compactness
assumption on one side makes the theorem break down.

(ii) Two directions of extension seem conceivable:

- The first would rely on some idea that our whole line of proof,
of reducing oneself to some case where Fubini's theorem could be applied,
is artificial, and that Fubini's theorem is irrelevant for this problem.
In that case, one ought to be able to remove from the assumptions the
last trace of Fubini's theorem - i.e. that the payoff function be
uniformly bounded either from below or from above, and one might try
to extend this to some "intrinsic" setting, i.e. essentially drop the
assumption that the strategy spaces are Hausdorff, and just ask, using
Alexander's subbase theorem, that the family of sets
$S_{t,\alpha} = \{s \in S \mid f(s,t) \geq \alpha\}$ $(t \in T, \alpha \in \underset{\sim}{R})$ has the finite
intersection property, and similarly for Player II.

- The other direction would on the contrary look at Fubini's
theorem as being basic, and consider that the "good" minmax theorem is
the corollary sub (B) in the proof (from which all other minmax statements
are easily obtained as corollaries - cfr. Section 4). So one would try
to show that, for any payoff function satisfying the assumptions of the
theorem, Fubini's theorem applies for any product of regular Borel
measures. Then the theorem would become an immediate corollary of the
statement sub (B). Furthermore, this would be a much more flexible tool,
in conjunction with the methods mentioned in Section 4, using the
stability properties of the set of functions that are measurable for

any product of tight probabilities (pointwise limits, algebraic operations, compositio.i, etc.).

The best result we know in this direction requires however, $f(s,t)$ to be continuous in each variable separately (and implies then, whenever S and T are Hausdorff spaces, that f is measurable for any tight probability on S × T - cfr. Bourbaki([1959] § 2, ex. 26). It is by the way the basic idea of a fundamental lemma underlying this theorem (that points in the closure of some set in C(K) are already in the closure of some countable subset of it) that we have used in part (D)(i) of the proof.

(iii) Motivations for this type of theorem are multiple.

(a) There is first the aesthetic motivation of obtaining the minmax theorem for mixed strategies under such assumptions that, by just adding the quasi-concavity-quasi-convexity assumption, one obtains Sion's assumptions for the existence of pure strategy solutions (adding a boundedness assumption to Sion's does not weaken his theorem).

(b) There is also the "effectiveness" point of view, that only discrete random variables can be effectively generated in finite time. (Any such discrete r.v. can be generated with a fair coin, by generating by successive tosses the successive bits of some random number x $(0 \leq x < 1)$, stopping as soon as it is clear that, for some n, $\sum_{i<n} p_i \leq x < \sum_{i\leq n} p_i$ and deciding then in favor of the n-th outcome: clearly a decision will be reached a.s. in finite time, and the n-th outcome will have probability p_n. This procedure can even be used with a biased coin, with unknown bias, by counting a pair of

successive tosses as one unit, giving a bit of "1" if first heads, then tails, a bit of "0" if first tails, then heads, and being inconclusive otherwise, in which case one should look to the next pair.)

It follows then that, for an operational concept of value, the players should be able to construct ε-optimal strategies where, in each information set, they are restricted to discrete mixtures.

In particular, for general minmax theorems, for normal form games, which may represent games with a single information set, one is led to the requirement of ε-optimal discrete mixtures. Under our assumptions, the players have ε-optimal finite mixtures, and the guaranteed payoff varies continuously with the probability vector used, so in any realistic model the player can play ε-optimally, even in bounded time.

(c) More important is the "safety" consideration, that, even neglecting the above, the player should always consider that his opponent might have an infinity of information sets at his disposal, or some analog device such as a continuous roulette wheel, and thus would be able to generate continuous random variables. In such a case, the evaluation of the expected payoff (even if players agree on some compact topologies on S and T, and to use only integration theory for regular Borel measures on compact spaces) would depend on the order of integration - except if one knows in addition that Fubini's theorem holds for the payoff function. For instance, players may think that the corollary sub (B) in the proof is the good minmax theorem; given a payoff function that would satisfy those assumptions for both players, player I might

find an optimal strategy that "guarantees" him +1, and similarly,
player II applying the same corollary for him might find an optimal
strategy that "guarantees" to him that the payoff will not exceed -1.
Obviously, realizing this, both players can only conclude that the only
thing they really can guarantee, is what they can guarantee with mixtures
with finite support. Since "-1" is always $\leq$ to "+1" this argument
is perfectly general. (By our theorem, one could, in this example,
have a strict inequality only for unbounded payoff functions; but still,
the theorem is needed for that, and anyway the argument remains, since
it depends only on the weak inequality $-1 \leq +1$.)

And things can be much worse, because nothing compels the player
to agree on some integration theory - or even on some topology for the
strategy spaces. You could even happen to be playing against Dubins
and Savage [1965], using finitely additive randomizations. In such cases,
only finite mixtures remain safe, unambiguous, and devoid of arbitrariness
(i.e. only such a solution depends only on the data of the problem, i.e.
the pure strategy sets -as sets- and the payoff function -as a real
valued function on the product of the pure strategy sets).

(d) The proof shows that the result is much easier to get for
compact metric spaces. Is it really worthwhile to make a substantially
bigger effort in order to get rid of the metrisability assumption?

A first answer would be that this simplifies the statement of
the theorem (one can drop "metric"), and that any effort in a proof
is worthwhile if it leads to a simpler (and more powerful) theorem.

A much more important reason is, however, that in any game where
a continuous variable can be observed before some action is taken, the
strategy spaces are non-metrisable. Certainly one does not want to
exclude such models from game theory. Besides the obvious cases
(observation of a price, or a quantity, or a continuous random variable),
this would also exclude any differential game (time being a continuous
variable) and any game with a continuum of players (just to define its
characteristic function, one needs the value of a zero sum game between
two opposing coalitions, where the strategy space of each coalition,
as an uncountable product, cannot be metrisable). Those problems
are amply documented in the literature; for instance, R.J. Aumann [1964]
suggests the use of behavioral strategies to get around this type of
problem; in other contexts (differential games, games with a continuum
of players, etc.) various other restrictions are imposed on the strategy sets.

Besides the inconvenience of requiring additional structure
(a topology, or a measurable structure), as was discussed in the previous
point, such procedures have the unpleasant feature of restricting the
strategy space -for instance, an arbitrary pure strategy is not necessarily
a behavioral strategy, since it may lack the measurability requirement.
For a minmax theorem, it is of course a net gain if one can show that
some player's (ε)-optimal strategies have in fact some additional
regularity property; however, it is disturbing when it is only shown
the the strategy is safe against some subclass of the opponent's strategies.
Indeed, the opponent should ideally not even be assumed to follow a
strategy, -he is just playing- and one would like the minmax theorem

to have essentially the same force as in the perfect information case,
i.e. that any "play" consistent with your ε-optimal strategy yields
a payoff $\geq v - \varepsilon$.

4. Other Minmax Theorems

A) Measure Theory (non-Hausdorff compact spaces)

For any compact space S, denote by C the convex cone of bounded
l.s.c. functions on S, and let $E = C \setminus C$. Denote by P the set of
monotonic real valued sublinear (i.e. positively homogeneous of degree
1 and subadditive $(p(x + y) \leq p(x) + p(y)))$ functions on C. P is
ordered in the usual way $(p_1 \leq p_2$ iff $p_1(f) \leq p_2(f)$ $\forall f \in C)$.

Definition: M(S) is the set of minimal elements of P.

Lemma 1: $\forall p \in P, \exists \mu \in M(S):$ $\mu \leq p$.

Proof: $\forall p \in P,$ $\forall f \in C$ let $\alpha \leq 0$ be such that $f \geq \alpha$.
Then $\forall q \in P$ s.t. $q \leq p$: $p(f) \geq q(f) \geq q(\alpha) \geq -q(-\alpha) \geq -p(-\alpha),$ so that the
set of possible values $q(f)$ is a bounded interval. Zorn's lemma
then yields a minimal such q.

Lemma 2: Any $\mu \in M(S)$ is a positive linear functional on E,
satisfying

$$\mu(f) = \inf \{\mu(g) \mid g \in C, g \geq f\} \quad \forall f \in E \quad .$$

Proof: Let $\tilde{\mu}: E \to R$ be defined by the above formula. Clearly
$\tilde{\mu}$ is real valued (if $f \geq \alpha$, then $\tilde{\mu}(f) \geq \tilde{\mu}(\alpha) \geq \mu(\alpha) > -\infty$). Further,
$\tilde{\mu}$ is obviously monotonic and sublinear, coinciding with μ on C.

The Hahn-Banach theorem says that any such $\tilde{\mu}$ is the supremum of a family of linear functionals. Any linear functional $\zeta \leq \tilde{\mu}$ is positive, because ≤ 0 on the negative functions. If there was a second such ζ, say $\tilde{\zeta}$, one would have $\zeta(f) \neq \tilde{\zeta}(f)$ for some $f \in C$. Then either ζ or $\tilde{\zeta}$, restricted to C, would be some element of P $\leq \mu$, and $\neq \mu$, thus μ would not be minimal. Therefore this ζ is unique, and thus coincides with $\tilde{\mu}$: $\tilde{\mu}$ is a positive linear functional on E.

Lemma 3: $M(S)$ is the set of positive linear functionals μ on E such that

$$\forall f \in C \quad, \quad \mu(-f) = \inf \{\mu(g) \mid g \in C, g \geq -f\} \quad .$$

Proof: One direction is given by Lemma 2. In the other direction, we have clearly $\mu \in P$, thus (Lemma 1) $\exists \nu \in M(S)$: $\nu(h) \leq \mu(h) \; \forall h \in C$. Thus $\nu(-f) \geq \mu(-f) = \inf \{\mu(g) \mid g \in C, g \geq -f\} \geq \inf \{\nu(g) \mid g \in C, g \geq -f\} = \nu(-f)$ (by Lemma 2), from which the equality of μ and ν.

Lemma 4: $M(S)$ is the set of regular Borel measures on S, i.e. the set of positive, bounded, countably additive measures on the Borel sets of S satisfying $\mu(A) = \sup \{\mu(F) \mid F \subseteq A, F \text{ closed}\}$ $= \inf \{\mu(O) \mid O \supseteq A, O \text{ open}\}$ for any μ-measurable set A.

Proof: Follows from a standard Daniell-type extension procedure. We sketch just a typical sequence of steps:

· Denote by LSC the set of l.s.c. functions with values in $R \cup \{+\infty\}$,

and $USC = -LSC$.

Let $\mu_1(f) = \sup \{\mu(g) \mid -g \in C, g \le f\}$ $\forall f \in LSC$

Let $\mu^*(f) = \inf \{\mu_1(g) \mid g \in LSC, g \ge f\}$ for any $\bar{R}$-valued f.

· Lemma 2 implies $\mu^* = \mu$ on E, and $\mu^* = \mu_1$ on LSC.

· Dini's theorem implies that, if $f_\alpha \in LSC$ is filtering increasing,
then

$$\mu^*(\lim f_\alpha) = \lim \mu^*(f_\alpha) \quad .$$

· It follows that $\mu^*(f + g) = \mu^*(f) + \mu^*(g)$ on LSC.

· The sublinearity of μ^* follows (avoiding $(+\infty) + (-\infty)$ right-hand
members, and using the convention $(0) \cdot (\infty) = 0$).

· Finally one gets: if h_n is any increasing sequence, with

$\lim \mu^*(h_n) > -\infty$, then $\mu^*(\lim h_n) = \lim \mu^*(h_n)$. (It is sufficient to

consider $\mu^*(h_n)$ finite; choose $f_n \in LSC$, $f_n \ge h_n$,

$\mu^*(f_n) \le \mu^*(h_n) + \epsilon \cdot 2^{-n}$. Let $\psi_n = \sup_{i \le n} f_i$. ψ_n is an increasing

sequence in LSC such that $\psi_n \ge h_n$. $\psi_n = \max(\psi_{n-1}, f_n)$ implies

$\mu^*(\psi_n) + \mu^*(h_{n-1}) \le \mu^*(\psi_n) + \mu^*(\min(f_n, \psi_{n-1})) = \mu^*(\psi_n + \min(f_n, \psi_{n-1}))$

$= \mu^*(f_n + \psi_{n-1}) = \mu^*(f_n) + \mu^*(\psi_{n-1})$, thus $\mu^*(\psi_n) - \mu^*(h_n)$

$\le [\mu^*(f_n) - \mu^*(h_n)] + [\mu^*(\psi_{n-1}) - \mu^*(h_{n-1})]$ and therefore

$\mu^*(\psi_n) - \mu^*(h_n) \le \sum_{i \le n} [\mu^*(f_i) - \mu^*(h_i)] \le \epsilon \sum_{i \le n} 2^{-i} \le \epsilon$, so that

$\lim \mu^*(h_n) \le \mu^*(\lim h_n) \le \mu^*(\lim \psi_n) = \lim \mu^*(\psi_n) \le \lim \mu^*(h_n) + \epsilon)$.

· It follows that μ^*, restricted to indicator functions, is an outer measure.

• Let $L = \{f \mid \mu^*(f) > -\infty, \mu^*(-f) > -\infty, \mu^*(f) + \mu^*(-f) \leq 0\}$.

By the sublinearity of μ^*, L is a vector space and μ^* is a linear functional on L. Further $E \subseteq L$ since μ^* coincides with μ on E, and in addition $f \in LSC$, $\mu^*(f) < \infty$ implies $f \in L$.

• Since for any open sets 0 and U, $I_0 \in L$, and $I_{0 \cap U} \in L$, we have also $I_{0 \setminus U} \in L$, so we get $\mu^*(0) = \mu^*(0 \cap U) + \mu^*(0 \setminus U)$. Thus, for any set A, since $\mu^*(A) = \inf \{\mu^*(0) \mid A \subseteq 0\}$, we get $\mu^*(A) \geq \mu^*(A \cap U) + \mu^*(A \setminus U)$, so that any open set U is μ^*-measurable and thus all Borel sets are μ^*-measurable.

• The formula $\mu(A) = \inf \{\mu(0) \mid A \subseteq 0, 0 \text{ open}\}$ for any μ^*-measurable set A implies $\mu(A) = \sup \{\mu(F) \mid F \subseteq A, F \text{ closed}\}$, and thus the μ^*-measurable sets are just the completion of the Borel sets, and μ is a regular Borel measure.

• Finally, $\int f \, d\mu = \mu^*(f)$ first for the convex cone spanned by the constants and the indicators of open sets, by linearity, next for all $f \in LSC$, by monotone convergence, and therefore for all $f \in L$ and in particular all $f \in E$. It also follows that $L = L_1(\mu)$.

• The regular Borel measure μ is unique, because its value on the open sets is determined.

• Conversely, clearly the integral for any regular Borel measure is a functional in $M(S)$.

The essential results of this section are summarized in the following:

Proposit$\ldots$: Denote by $M(S)$ the set of positive, regular
Borel measures on S. Then:

• $\forall\, p \in P \;\exists\, \mu \in M(S)$: $\mu \leq p$ on C (Lemma 1).

• $M(S)$ is a convex cone (and a complete lattice) (immediate from Lemma 4).

• If the sum of 2 positive linear functionals on E is in $M(S)$, each
one is also (immediate from Lemma 3).

• Define the "weak*-topology" on $M(S)$ as the coarsest topology for
which $\int f d\mu$ is lowersemicontinuous $\forall\, f \in C$, and thus for all l.s.c. f.
Then addition and scalar multiplication are continuous, points are
closed and all sets $\{\mu\,|\,\mu(1) = \lambda\}$ and $\{\mu\,|\,\mu(1) \leq \lambda\}$ $(\lambda > 0)$ are
closed and compact.

Proof: The continuity of addition and scalar multiplication is
immediate. $\{\mu\}$ is closed because, if $\tilde{\mu}$ is in the closure of μ,
one has $\tilde{\mu}(f) \leq \mu(f)\;\forall\, f \in C$, thus $\tilde{\mu} = \mu$ by the minimality of μ.

Since all constants belong to C, there only remains to prove
the compactness of $\{\mu\,|\,\mu(1) \leq \lambda\}$. For any ultrafilter on this set,
let ϕ denote its pointwise limit in the set of positive linear functionals
on E. By Lemma 1, $\exists\, \nu \in M(S)$ with $\nu \leq \phi$ on C: ν is a limit
point in $M(S)$.

Note that the above applies whenever C is a lattice and convex
cone of bounded functions on some set S, containing the constants and
such that $f_i \in C$, $f_i \leq f_{i+1} \leq 0$ implies $\lim f_i \in C$, and $\lim f_i > -1$
implies $\exists\, i$: $f_i > -1$. The Borel sets are then interpreted as the
σ-field generated by C, and the regularity is with respect to the

$\{f \leq 0\}$ $(f \in C)$ as closed sets. (Dini's theorem should be used only for sequences then.)

In particular, everything applies as soon as S is countably compact (any sequence has a cluster point). Compactness only yields the additional τ-smoothness property: $\mu(\underset{\alpha}{\cup} 0_\alpha) = \underset{\alpha}{\sup} \mu(0_\alpha)$ for any increasing net of open sets 0_α.

In the particular case where S is Hausdorff, i.e., $\forall f, g \in C$ s.t. $f > -g$ $\exists h$: $-g \leq h \leq f$, h continuous, the above results yield Riesz' theorem.

We now obtain also, using standard techniques, a Fubini theorem (the same theorem and proof obviously holds for arbitrary products, finite or infinite; the minmax theorem is however, concerned only with products of two factors. The contribution of the theorem is obviously to get the measure on the Borel σ-field of the product, instead of the product σ-field):

Proposition 2: Let K_1 and K_2 denote two compact spaces, $K = K_1 \times K_2$. Let $\mu_1 \in M(K_1)$, $\mu_2 \in M(K_2)$. Then

(a) There exists a unique $\mu \in M(K)$, denoted $\mu_1 \circledast \mu_2$, such that $\mu(F_1 \times F_2) = \mu_1(F_1)\mu_2(F_2)$ $\forall$ F_i closed in K_i.

(b) For any lowersemicontinuous f, there exists a sequence of functions $\psi_i = \epsilon_i I_{F_1^i \times F_2^i}$ with $\epsilon_i > 0$, F_j^i closed in K_j, and a constant function $\psi_0 \leq 0$, such that

$$\sum_i \psi_i \leq f \quad \text{and} \quad \int f d\mu = \sum \int \psi_i d\mu \quad .$$

(c) For any μ-quasi-integrable f one has that

- for μ_1- almost every x, $f(x,.)$ is μ_2-quasi-integrable.

- $\int f(x,y) d\mu_2(y)$ is μ_1-quasi-integrable (and l.s.c. if f is)

- $\int [\int f(x,y) d\mu_2(y)] d\mu_1(x) = \int f \, d\mu$.

(An extended real valued function f called μ-quasi-integrable if it is μ-measurable and either $\int f^+ d\mu \neq \infty$ or $\int f^- d\mu \neq \infty$).

Proof: Denote by $\tilde{\mu}$ the product measure on the product of the Borel σ-fields; let $\bar{\mu}$ be a positive linear functional on all bounded functions that extends $\int(.) d\tilde{\mu}$, and let (Lemma 1) $\bar{\bar{\mu}} \in M(K)$ minorize $\bar{\mu}$ on C. Then we have

$$\bar{\bar{\mu}}(O_1 \times O_2) \leq \bar{\mu}(O_1 \times O_2) = \tilde{\mu}(O_1 \times O_2) = \mu_1(O_1)\mu_2(O_2)$$
$$\text{for all } O_i \text{ open in } K_i, \text{ and}$$

$$\bar{\bar{\mu}}(F_1 \times F_2) \geq \bar{\mu}(F_1 \times F_2) = \tilde{\mu}(F_1 \times F_2) = \mu_1(F_1)\mu_2(F_2)$$
$$\text{for all } F_i \text{ closed in } K_i.$$

Using the regularity of μ_i, it follows that, for any μ_i-measurable sets A_i, $\bar{\bar{\mu}}(A_1 \times A_2) = \mu_1(A_1)\mu_2(A_2)$.

Thus the product measure $\tilde{\mu}$ can be extended to a regular Borel measure. By the regularity of μ_1 and μ_2, any Borel measure μ satisfying $\mu(F_1 \times F_2) = \mu_1(F_1)\mu_2(F_2)$ will satisfy $\mu(A_1 \times A_2) \geq \mu_1(A_1)\mu_2(A_2)$ for any Borel sets A_i, and thus going to complements, the inverse inequality: it will be an extension of $\tilde{\mu}$. Since any open set O is the limit of the increasing net of sets O_α, where the sets O_α are all finite unions of products $O_1 \times O_2 \subseteq O$, and thus $\tilde{\mu}$-measurable, the regularity of μ will imply that μ is uniquely determined on all open sets, and thus on all Borel sets.

This proves statement (a), and (b) is obtained by pursuing a bit the same argument (representing the O_α as finite disjoint unions of products of Borel sets, and using there the regularity of the μ_i's, going from indicator functions of open sets to l.s.c. functions f, one obtains a finite sequence ψ_i with $\sum_i \psi_i \leq f$ and $\sum \int \psi_i d\mu$ as close as required to $\int f d\mu$. Iterating this conclusion with the l.s.c. function $f - \sum \psi_i$ yields (b)).

(c) is proved by first noting its truth when $f = I_{O_\alpha}$, next, using the regularity of all measures, that it remains therefore true for indicators of open sets, and hence for all lowersemicontinuous f. The general statement follows then because, for any quasi-integrable f,
$$\int f d\mu = \inf \{\int g d\mu \mid g \text{ l.s.c. } \geq f\} = \sup \{\int h d\mu \mid h \text{ u.s.c. } \leq f\}; \text{ this}$$
was proved in Lemma 4.

B) A Basic Tool

We return now to the corollary sub (B) of our minmax theorem, dropping the Hausdorff assumption on S. Remark that, for any τ with finite support, $f(s,\tau)$ is u.s.c. in s; it therefore achieves its maximum, and $\max_s f(s,\tau) = \max_{\sigma \in M(S)} f(\sigma,\tau)$. Let $\bar{v} = \inf_\tau \max_\sigma f(\sigma,\tau)$ (τ ranging over probabilities with finite support). By part (A) of the proof there exists, for any finite subset $\tilde{T}$ of T, a probability σ with finite support on S such that $\min_{t \in \tilde{T}} f(\sigma,t) \geq \bar{v}$. Since $f(.,t)$ is u.s.c., and σ is a positive linear functional on E, there exists by Lemma 1, $\tilde{\sigma} \in M(S)$ with $\tilde{\sigma}(g) \geq \sigma(g)$ for all u.s.c. g. In particular, $\tilde{\sigma}(1) = \sigma(1) = 1$, and $\min_{t \in \tilde{T}} f(\tilde{\sigma},t) \geq \bar{v}$. Let $\sum_{\tilde{T}} = \{\sigma \in M(S) \mid \sigma(1) = 1 \text{ and } f(\tilde{\sigma},t) \geq \bar{v}$ $\forall t \in \tilde{T}\}$.

$\sum_{\widetilde{T}}$ is obviously closed in $M(S)$, thus, by Proposition 1, the sets $\sum_{\widetilde{T}}$ form a decreasing net of nonempty, closed, compact sets, and therefore have a nonempty intersection. Any σ in the intersection fills the bill.

Observe that it follows from this that we can phrase the assumptions of that corollary in a fully intrinsic way, using Alexander's subbase theorem:

Theorem 2: Denote by S and T two sets, $f: S \times T \to R \cup \{-\infty\}$. For any $\alpha \in \underset{\sim}{R}$ and $t \in T$, let $S_{t,\alpha} = \{s \in S \mid f(s,t) \geq \alpha\}$. If the family of sets $S_{t,\alpha}$ has the finite intersection property, and if $M(S)$ denotes the set of regular Borel probabilities on S endowed with the coarsest topology for which the functions $f(.,t)$ $(t \in T)$ are u.s.c., then

$$\max_{\sigma \in M(S)} \ \inf_{t \in T} f(\sigma, t) = \inf_{\tau \in \overline{T}_f} \ \max_{s \in S} f(s, \tau) \quad .$$

Remarks:

1) The finite intersection property can be rephrased as asking that any pointwise limit of pure strategies, i.e. of functions $f(s,.)$, be dominated by some pure strategy, i.e. by some function $f(s_0,.)$.

2) This property is substantially weaker than the usual compactness assumption. For instance, if T is a single point, it just asks that $f(s)$ attains its maximum.

3) Using the remark after Proposition 1, it is sufficient to ask that the class of sets $S_{t,\alpha}$ be countably compact, i.e. that any countable family of such sets has the finite intersection property. In that case $M(S)$ becomes the set of probabilities on the σ-field

generated by the functions $f(.,t)$, regular w.r.t. the countable

intersections of finite unions of sets S_t, (in particular, if S with

its coarsest topology is countably compact, M(S) is just the set of

regular Borel probabilities on S).

This amounts to ask that, for any countable subset $\tilde{T}$ of T,

any pointwise limit of pure strategies s_n be dominated on $\tilde{T}$ by

some pure strategy s_0.

4) Given the above measure theory, including Fubini, essentially

our whole proof of Section 2 would go through without the Hausdorff

assumption, and thus give the corresponding "intrinsic" result.

Indeed, the use of continuous functions in part "D" has nothing

essential; lowersemicontinuous ones would do as well, giving a reduction

to the case where T is compact with countable base, in which case the

proof sub (C) works just as well. The only troublesome point lies in

the last sentence sub (ii) of case (D) where the regularity of the

topology ("every point has a basis of closed neighborhoods") seems to

be used in an essential way.

Anyways, it goes through if one assumes that one of the spaces

S and T either has a countable basis or is Hausdorff.

C) Other Techniques from the Literature

Most results of the literature (except of course Sion's) are

obtained, or are at least obtainable, by applying to some particular

case of Theorem 2 one of the two following generalization techniques:

1) The first one goes back to Wald. It states that, if for

any $\varepsilon > 0$ it is possible to find subsets S_ε of S and T_ε of

T such that, by some independent argument, the game restricted to S_ε

and T_ϵ has a value, and such that $\forall s \in S$, $\exists s' \in S_\epsilon$: $f(s,t) \leq$
$f(s',t) + \epsilon$ $\forall t \in T_\epsilon$, and similarly $\forall t \in T$, $\exists t' \in T_\epsilon$: $\forall s \in S_\epsilon$
$f(s,t) \geq f(s,t') - \epsilon$, then the given game has a value.

2) The other idea is based on Karlin, and amounts essentially
to using the monotone convergence theorem, or Fatou's lemma.

For instance, after applying Theorem 2 to some game, and having
found the value v and player I's optimal strategy μ, one looks for
some class C of functions $\phi(s)$ such that $\int \phi(s) d\mu \geq v$. Say C
contains all bounded measurable functions that are minorized by some
$f(.,t)$ $(t \in T)$ and their convex combinations, and also the limit
of any decreasing sequence ϕ_n of such functions (one could still add
all functions ψ which are, for any regular Borel probability μ,
in the equivalence class of some $\phi \in C)^{1/}$.

Then any game $\tilde{f}(s,t)$ such that $\tilde{f} \leq f$ and $\forall t$, $\tilde{f}(.,t) \in C$
would have the same value and optimal strategy.

Usually f is constructed from $\tilde{f}$ by taking the smallest u.s.c.
function majorizing it, but sometimes the argument has to be applied
both ways.

To illustrate, we give a typical application: S and T are
compact metric, f is a bounded measurable (i.e. measurable for any
product measure) function on $S \times T$ such that, if $E = \{(s,t) \mid f$
is not continuous in s or in t at $(s,t)\}$, then $\forall s$, $\#\{t \mid (s,t) \in E\} \leq 1$
and $\forall t$, $\#\{s \mid (s,t) \in E\} \leq 1$. (Remark that measurability would follow
for instance if we had, denoting by $\bar{E}$ the (F_σ) set of points of
discontinuity of f, $\forall s \{t \mid (s,t) \in \tilde{E}\}$ and $\forall t \{s \mid (s,t) \in \tilde{E}\}$
are at most countable.)

Such a game has a value.

Indeed, let $\phi_1(s_0,t_0) = \lim\sup_{\substack{s \to s_0 \\ s \neq s_0}} f(s,t_0)$, $\phi_2(s_0,t_0) = \lim\inf_{\substack{t \to t_0 \\ t \neq t_0}} f(s_0,t)$.

Consider an optimal strategy σ of player I in the game with payoff

$f \vee \phi_1$ (Theorem 2). $\forall t_0 \in T$, by considering an appropriate sequence

t_i converging to t_0, one can have $\lim_{i \to \infty} (f \vee \phi_1)(s,t_i) = [\phi_2 \wedge (f \vee \phi_1)]$

(s,t_0). Thus, by the above argument, say in the form of Fatou's lemma,

σ is still an optimal strategy of player I for $[\phi_2 \wedge (f \vee \phi_1)]$, guaranteeing

the same value v_1, and player II's ϵ-optimal strategy with finite

support τ_ϵ guarantees the same v_1 for $(f \vee \phi_1)$.

Inverting the roles of the players, we get a value v_2 for

both $f \wedge \phi_2$ and $[\phi_1 \vee (f \wedge \phi_2)]$, an optimal strategy τ for II

and an ϵ-optimal strategy with finite support σ_ϵ for I. But

$\phi_1 \vee (f \wedge \phi_2) \geq \phi_2 \wedge (f \vee \phi_1)$, so, by applying Fubini's theorem to

$\sigma \otimes \tau$ and those payoff functions, we get $v_2 \geq v_1$. Since

$f \vee \phi_1 \geq f \geq f \wedge \phi_2$, we have $v_2 = v_1 = v$, and σ_ϵ and τ_ϵ guarantee

v in those 3 games, so in f.

Karlin's "general game of timing of class II" (Karlin, [1959],

Chap. V, Ex. 20), falls in this category.

Similarly, assume S and T are compact, and $f(s,t)$ is

bounded and Borel-measurable on $S \times T$. Assume $\exists S^0 \subseteq S$ and $T^0 \subseteq T$

such that $f(s,.)$ is l.s.c. on T for $s \in S^0$, $f(.,t)$ is u.s.c. on

S for $t \in T^0$, and such that $\forall s \in S \; \exists s_n \in S^0$ with $\lim\inf_{n \to \infty} f(s_n,t)$

$\geq f(s,t) \; \forall t \in T$, and that $\forall t \in T \; \exists t_n \in T^0$ with

$\lim\sup_{n \to \infty} f(s,t_n) \leq f(s,t) \; \forall s \in S$. Then this game has a value,

and both players have ϵ-optimal strategies with finite support carried

by S^0 and T^0 respectively.

Indeed, Theorem 2 yields a value $\bar{v}$ for the game on $S \times T^0$, and by Fatou's lemma, player I's optimal strategy is still safe against all $t \in T$. Similarly one can apply Theorem 2 and next Fatou's lemma to the game on $S^0 \times T$, with value $\underline{v}$. Fubini's theorem applied to f and the product of the optimal strategies yields then $\underline{v} = \bar{v}$, hence the result.

C. Waternaux [1983]'s "auxiliary game" is of this type.

Most other classical examples (like all examples in Karlin [1950], Restrepo's "general silent duel" or Karlin's "two machine-gun duel") can be shown to have a value by the same technique, applied in a more or less similar (and often easier) way.

Footnotes

1/ If this is done, the resulting class C is identical to the
set of all functions ϕ, such that $\forall$ n, $\phi v(-n)$ is in the closed
convex hull of the set of bounded measurable function $\geq$ some
$f(.,t)$, in the space of all bounded universally measurable
functions in duality with the space of regular Borel measures
on S. This shows that our technique is really equivalent to
Karlin's apparently more powerful closure methods (Karlin, [1950]).

The only point to show is that the class $\tilde{C}$ of bounded functions
in C is closed, it is thus sufficient to show closedness in
$L_\infty(\mu)$ $\sigma(L_\infty(\mu),L_1(\mu))$.   By the Krein-Smulian theorem on weak*-
closed convex sets, it is sufficient to show that its intersection
with any ball of L_∞ is $\tau(L_\infty,L_1)$-closed.   Since the Mackey
topology coincides on balls of L_∞ with the topology of
convergence in measure (this result of Grothendieck follows
easily from Dunford-Pettis' equiintegrability criterion for
weak compactness in L_1), it follows from Egorov's theorem that
it is sufficient to show that the limit of any uniformly bounded
a.e. convergent sequence (g_n) in $\tilde{C}$ is in $\tilde{C}$.

There is obviously no loss in assuming further that each g_n
is larger than some convex combination of functions $f(.,t)$.
Then lim sup g_n is obviously in $\tilde{C}$.
