19. ABSTRACT (Continue on reverse if necessary and identify by block number)					
This report covers the results from the first year of a two-year carcinogenicity bioassay of the tissue adhesive, isobutyl 2-cyanoacrylate (IBC). Four hundred seven 6-week old Fischer-344 rats were randomized into three groups (control, 10 μl IBC, and 100 μl IBC), each group containing both male and female animals. The IBC was administered by surgical implantation of liquid monomer directly onto the ventral capsule of the liver. The monomer was allowed to polymerize before two-layer closure of the abdominal incision. Control animals received 100 μl of isotonic saline also by surgical implantation. Twenty-five animals were removed from the study during the first week after surgery because of underweight condition or post operative complications. All animals were examined daily and weighed and palpated monthly. The animals presented with (Continued on Reverse)

Item 19 continued:

a variety of transitory clinical signs sporadically throughout the year in addition to the more permanent sequelae of the surgical procedure (xyphoid protuberance, corneal opacity). These signs were observed in all dose groups and could not be attributed to compound administration. The weight gain of the two IBC treatment groups was comparable to that recorded for the control group. During the first year, 17 animals died or were sacrificed; three were unscheduled deaths and 14 were unscheduled sacrifices. At the end of the first year 60 animals, 10 males and 10 females from each of the three groups, were selected randomly for a scheduled interim sacrifice. Three hundred and five animals remained on study at the start of the second year.

A total of 77 animals (17 unscheduled and 60 scheduled) were evaluated at necropsy during the first year. Fourteen of 14 unscheduled animals and 39 of 40 scheduled animals that received the IBC had fibrotic adhesions between the liver and the omentum, peritoneal membrane, diaphragm, stomach, skin, and/or intestine. These lesions were characterized histologically as foreign body granulomatous reactions. Nine tumors were observed in three unscheduled (total four tumors) and five scheduled animals. The unscheduled animal tumors included an atriocaval epithelial mesothelioma (10 ul IBC male), a mononuclear cell leukemia of splenic origin (10 ul IBC female), and a pituitary adenoma and mononuclear cell leukemia (100 ul IBC female). The scheduled animal tumors included an endometrial stromal polyp (10 ul IBC female), testicular mesothelioma (10 ul IBC male), adrenal gland cortical adenoma (10 ul IBC male), and pituitary adenomas (control and 10 ul IBC males). These tumors were spontaneous lesions and were considered incidental to IBC treatment. All other gross or histopathological findings were also considered incidental to IBC treatment or were sequelae of the surgical procedure.

Results of this study indicate that IBC has no effect on survival, weight gain, or the clinical condition of rats during the first year following its implantation. The only gross or histopathological finding observed in the first year attributed to the IBC treatment was the presence of adhesions on and a granulomatous reaction of the liver and those adjacent organs that came in contact with the IBC. No tumors were observed during the first year that could be attributed to IBC treatment.

Glossary of Tumor, Compound Related Findings and Frequently
Observed Incidental Lesions for Isobutyl 2-Cyanoacrylate
Carcinogenicity Assay - GLP Study 83009

RAT CHRONIC RENAL DISEASE

Rat chronic renal disease is prevalent in many strains of rat including the Fischer 344. The cause of the disease is unknown. It is a progressive disease in which the incidence and severity increase with age. Microscopic lesions may occur as early as three months, but severe lesions are rarely found in rats less than one year of age. Tubules, glomeruli, interstitium and small blood vessels are all involved.

Interstitial changes progress from small perivascular aggregates of lymphocytes in between the tubules to interstitial fibrosis and increased numbers of mononuclear leukocytes in later stages. Tubular changes start with dilation and filling of tubular lumens with hyaline material. Tubular epithelial cells eventually show degenerative changes such as vacuolation, accumulation of hyaline droplets and necrosis in severe cases. These cells may range from being flattened to being hyperplastic (during regenerative attempts) when they are large and pleomorphic. Tubular basement membranes frequently thicken and ultimately both cystic dilatation and tubular atrophy occur.

Glomerular changes usually become apparent by light microscopy a little later than tubulo-interstitial changes. Thickening of Bowman's capsular basement membranes, pericapsular fibrosis, increased numbers of cells in the glomerular tuft, mild thickening of capillary walls and glomerular mesangial matrix increase are early changes, which progress to glomerular sclerosis and/or atrophy with cystic dilatation of Bowman's space.

Hyalinization of the walls of small blood vessels and widespread mineralization of tubules, basement membranes, and necrotic epithelial cells are present in the severe stage of the disease.

Scoring Criteria: Rat Chronic Renal Disease

Score

- | | |
|-----------------|--|
| 1
(trace) | Occasional aggregates of lymphocytes are present or adjacent to small blood vessels primarily located in the corticomedullary junctions. Low numbers of lymphocytes may be present in the interstitium between tubules. An occasional tubule may contain a hyaline cast or be dilated. Mineralization may be minimally present. |
| 2
(mild) | From a few to several tubules may be dilated and/or contain hyaline material. Tubular epithelium may have degenerative changes. Thickening may be present in the region of tubular and Bowman's capsular basement membranes. Minimal interstitial fibrosis may be present around Bowman's capsule and tubules. Glomeruli may be hypercellular and a rare atrophic glomerulus may be present. Increased numbers of lymphocytes may be present in the interstitium. The renal capsule is still smooth. Changes may involve up to one fourth of the area examined. |
| 3
(moderate) | Numerous tubules may be dilated or contain hyaline material. Occasional tubules may be either cystic or atrophied. Tubular regeneration may be apparent. Interstitial fibrosis is present as is periglomerular and peritubular basement membrane thickening. Glomerular tufts may have thickening of capillary loops, increased mesangial matrix, increased cellularity and occasional areas of sclerosis. Occasional glomeruli may be completely sclerotic or atrophied with or without cystic dilatation of Bowman's space. Capsular surfaces can be mildly irregular and up to one half of the area examined may be involved. |

Score

- 4
(marked) Tubular dilatation and hyaline casts are spread throughout the section. Renal tubular necrosis and widespread mineralization may be present. Interstitial fibrosis will be apparent throughout the cortex. Cystic tubules and Bowman's spaces will be numerous. Glomerular changes will be apparent and widespread. Capsular surfaces will be irregular. Hyalinization of small vessel walls may be apparent.

CARDIOMYOPATHY OF THE FISCHER F344 RAT

Cardiomyopathy is a common disease of aging F344 rats. Younger rats may have a mild to moderate focal myocarditis. As the rats age the disease progresses to myocardial degeneration characterized by vacuolation and atrophy of muscle fibers. This is followed by fibrosis and loss of myofiber. All portions of the heart are not uniformly affected.

Grading of Cardiomyopathy

Score

- 1
(trace) From one to five small (2 mm in diameter) foci of lymphocytic infiltrates between myocardial fibers or around vessels in the myocardium.
- 2
(mild) From 6 to 10 foci of lymphocytic infiltration and/or minimal to mild vacuolar changes in cardiomyofibers. Fibrosis that includes less than one-quarter section.
- 3
(moderate) More than 10 foci of lymphocytic infiltration. Moderate to severe vacuolation of cardiomyofibers. Minimal to mild myofiber atrophy. Minimal to mild fibrosis in not more than one half of section.
- 4
(marked) Greater than one third of the section involved. Moderate to severe myofiber atrophy and fibrosis.

HEPATITIS

Hepatitis consists of random, multifocal, small aggregates of lymphocytes, PMN, mononuclear and macrophage within the hepatic parenchyma. Hepatocellular degeneration and loss may accompany this change. Minimal to severe 3 foci-minimal.

BILE DUCT HYPERPLASIA

Aging F344 rats frequently have foci of increased numbers of bile ducts in portal areas. Early lymphocytic pericholangitis is seen. Later bile duct proliferation is apparent. Fibrosis may or may not ensue.

Scoring Bile Duct Hyperplasia

Score

1 (trace)	1 to 3 portal areas have hyperplastic bile ducts.
2 (mild)	4 to 9 portal areas have hyperplastic bile ducts.
3 (moderate)	More than 9 portal areas have hyperplastic bile ducts. Pericholangiolar fibrosis and minimal sclerosis are present.
4 (marked)	Pericholangiolar fibrosis is from moderate to severe, with from mild to severe sclerosis in addition to hyperplasia.

NONNEOPLASTIC FOCI AND AREAS OF CELLULAR ALTERATIONS IN RAT LIVERS

Three distinctive types of cellular alteration called "foci" or "areas" may be present in rat livers. They are more common in older rats, but they can be seen in rats less than one year old. These lesions are named for the morphology of their cellular composition which may be clear cell, acidophilic (ground glass) and basophilic. These lesions are usually uniform in cell type, but they may occasionally contain mixtures of cell types.

A lesion smaller than or equal to the size of a lobule is called a focus. A lesion larger than a lobule is called an area. The architected pattern of the lesion varies little from the normal. The cellular appearance and staining reaction within the lesion is distinctly different from the adjacent normal cells. Hepatic cords of the lesion merge imperceptibly with those of the surrounding tissue without compressing them.

Foci and areas of cellular alteration can occur singly or in multiples, and the types can occur singly or in any combination. Their distribution throughout the liver is not uniform, and they may coexist with any other possible type of hepatic lesion.

Clear Cell Focus (area)

Appears as an area of clear pale cells sharply delineated from surrounding liver tissue. The cells have an empty zone around the nucleus which contains glycogen. Cells may be enlarged or of normal cell size.

Acidophilic Cell Focus (area)

Appears as an acidophilic staining area and the cellular cytoplasm has the appearance of ground glass. There is usually cellular enlargement with enlarged nuclei and prominent nucleoli. Inclusions may be present in the cytoplasm. The cords may be slightly irregular.

Basophilic Cell Focus (area)

Appears as an area of basophilic staining cells which are smaller than normal. The plates may be tortuous due to increased numbers of cells.

Mixed Cell Focus (area)

The mixed cell focus lesion may contain mixtures of any of the three types described previously.

All types of foci and areas will be considered equal for scoring purposes. An acidophilic focus and a basophilic focus would be counted as two foci.

Score

- | | |
|-----------------|--|
| 1
(trace) | One focus. |
| 2
(mild) | Two to four foci - or - one area alone or in combination with from one to four foci. |
| 3
(moderate) | Five to eight foci - or - two to three areas alone or two areas in combination with from one to four foci. |
| 4
(marked) | Eight or more foci - or - four or more areas alone or three areas in combination with from one to four foci. |

CHARACTERIZATION OF THE LESION PRODUCED LOCALLY BY
BUCRYLATE®

The Bucrylate® is surrounded by a capsule of fibrous connective tissue. Inflammatory responses may or may not be present; however, when present, inflammation is characterized by macrophages and multinucleated giant cells adjacent to the Bucrylate®. Some small regions of the hepatic capsular surface are surrounded and sequestered by fibrous tissue. The hepatic tissue in these areas is usually atrophied and only a few islands of hepatocytes or an occasional bile duct remains.

Where the liver is adhered to adjacent structures, such as diaphragm, abdominal wall or intestine, the Bucrylate® is sequestered by fibrous connective tissue. The adjacent structures are joined by this fibrous tissue.

This lesion will be reported only as present (+) or absent (-).

MINERALIZATION OF PULMONARY ARTERIES AND AORTA

Focal, dense mineral deposits are frequently observed in the larger pulmonary arteries of F344 and other strains of rats. They are located beneath the endothelium in the vessel wall. Their etiology is unknown and they are not considered clinically important.

Scoring will be as follows:

Score

- | | |
|-----------------|--|
| 1
(trace) | A single small focus of mineral which produces minimal distortion of the vessel wall. |
| 2
(mild) | Two to three small foci which produce minimal distortion to the vessel wall. |
| 3
(moderate) | Four or more small foci which distort the vessel wall minimally or one larger focus which causes moderate distortion of the vessel wall. |
| 4
(marked) | More than one large focus which causes moderate distortion of the vessel wall. |

TUMORS

Generally tumors will be reported as being present in a tissue. Severity is not indicated.

ATRIOCAVAL EPITHELIAL MESOTHELIOMA

Atriocaval epithelial mesothelioma is an infiltrative tumor of the myocardium. It is composed of glandular acini and anastomosing tubules lined primarily by cuboidal epithelial cells. The neoplastic structures may extend to the endocardial surface and are frequently filled with blood, blood clots, hemoglobin crystals and degenerating RBC's. The cells contain a modest amount of eosinophilic cytoplasm, round to oval nuclei with prominent nucleoli, and fine chromatin. The neoplastic cells may form clumps or sheets in some areas. Mitotic figures may be present in moderate numbers.

LARGE GRANULAR LYMPHOCYTE LEUKEMIA (MONONUCLEAR CELL LEUKEMIA)

Large granular lymphocyte leukemia is usually seen in peripheral blood late in the course of disease; leukocyte counts are usually less than 100,000/mm³. These cells may be seen in the blood vessels and sinusoids of various organs. They are characterized by dense pleomorphic nuclei and eosinophilic cytoplasm which is occasionally granular. Microscopic lesions are frequently found in the spleen, liver and lung. The kidney, heart and pancreas are less frequently involved. Lymph nodes may be infiltrated by neoplastic cells.

COMPOUND RELATED INFLAMMATORY REACTION

This lesion is quite similar regardless of location or organ involved. The Bucrylate® is surrounded by fibrous connective tissue. Usually there is a mild inflammatory response consisting of macrophages and multinucleated foreign body giant cells adjacent to the fibrous capsule. The presence of the material and associated fibrous reaction may cause secondary changes such as atrophy of parenchyma or compromise of circulation and its secondary consequences.

PITUITARY GLAND ADENOMA

Adenomas of the anterior pituitary gland are very common in aged F344 rats. These lesions vary greatly in size from small microscopic proliferations to large masses that compress adjacent brain tissue. The microscopic appearance and cellular morphology are also variable. Cells may be arranged in sheets, nests, or acini; they are usually nearly spherical cellular proliferations which compress adjacent normal pituitary tissue. The cellular component may be either acidophils, basophils or chromophobes with variable cellular pleomorphism and tinctorial characteristics. Most pituitary adenomas are quite vascular and vascular dilatation and hemorrhage are very common. Occasionally pituitary adenomas may be composed of two or more nodules, each having different cellular morphology.

ADRENAL GLAND CORTICAL ADENOMA

Adenomas of the adrenal cortex are very common in old F344 rats. These lesions vary greatly in size from small microscopic lesions to large masses which involve large areas of the cortex. Cortical adenomas are discrete areas of cellular proliferation of normal adrenal cortical cells, or they may vary considerably in size, staining characteristics, and cellular arrangement. Frequently cells in adenomas are highly vacuolated. Nuclei may be hyperchromatic and larger than normal. Few mitotic figures are present. Adrenal cortical adenomas are highly vascular, and sinusoidal dilatation and hemorrhage is common.

UTERUS-ENDOMETRIAL STROMAL POLYP

Endometrial stromal polyps are fairly common in older female F344 rats. These lesions consist of polypoid masses which protrude from the uterine wall into the uterine lumen. The mass is covered by typical endometrial surface epithelium which may be eroded in some areas. Relatively normal appearing uterine glands, some of which are dilated and cystic, are common. The glands are surrounded by a dense fibrovascular stroma containing abundant collagen and numerous blood vessels. Some smooth muscle cells may be present. Mitotic figures may be present in both stroma and epithelium but these are usually few in number. Focal ulceration of epithelium accompanied by inflammatory cell infiltration may be present.

TESTIS-MESOTHELIOMA

Mesotheliomas of the tunica vaginalis occur occasionally in the testes of male F344 rats. These lesions are located on the serosal surface of the testis or epididymis and are usually unilateral. They are composed of multiple, papillary fronds arising from the serosal surface. The papillary structures have a supporting connective tissue stalk containing blood vessels and are covered by mesothelial cells. The lining usually consists of a single layer of mesothelial cells, but occasionally these cells are piled up into small nodular proliferations. Mitotic figures are infrequent.

Individual Animal Pathology Reports

The Pathology animal number is followed by a three digit toxicology "in-life" animal number in parenthesis. This Toxicology number is a shortened version of the 84D00--- numbering system referenced in the text and Appendix B. The dates of death on these reports for interim sacrifice females are recorded as 28 Jan 1985 when in fact the females were necropsied on 29 Jan 1985. All organs were weighed on the date the necropsy occurred. The date given under the organ weight section of each individual report is the date the hand recorded data were entered into the computer.
