A Numerical Model for the Computation of Radiance Distributions in Natural Waters with Wind-Roughened Surfaces, Part II: Users' Guide and Code Listing

Curtis D. Mobley*

ABSTRACT. This report is a users' guide for and listing of the FORTRAN V computer code that implements a numerical procedure for computing radiance distributions in natural waters. The mathematical details of the numerical radiance model are described in a companion report (A Numerical Model for the Computation of Radiance Distributions in Natural Waters with Wind-Roughened Surfaces, by Curtis D. Mobley and Rudolph W. Preisendorfer, NOAA Technical Memorandum ERL PMEL-75). The present report describes how to run the computer model and therefore addresses questions such as which routines perform which calculations, what input is required by the various programs, and what is the file structure of the overall program.

1. INTRODUCTION

General knowledge of the radiance distribution in a natural hydrosol, such as a lake or ocean, is a prerequisite for the solution of more specific problems in underwater visibility, remote sensing, photosynthesis, or climatology. Moreover, since radiance is the fundamental radiometric quantity, if the radiance distribution is known, then all other quantities of interest, such as the irradiances and K-functions, are easily computed.

With the above incentives, a numerical model, called the *Natural Hydrosol Model* or *NHM*, was developed, based on the following assumptions:

- (1) The water body is a plane-parallel medium which
 - (a) has no internal light sources, and is non-fluorescent
 - (b) is directionally isotropic,
 - (c) is laterally homogeneous, but is inhomogeneous with depth.
- (2) The upper boundary is the random air-water interface, which is wind-ruffled, laterally homogeneous, and azimuthally anisotropic.
- (3) The lower boundary is a surface whose reflectance is azimuthally isotropic. This boundary may be either the physical bottom of an optically shallow water body, or a plane in an optically infinitely deep water body, below which the water is homogeneous with depth.
- (4) There is radiant flux incident downward on the upper boundary. There is no radiant flux incident upward on the lower boundary.

* Joint Institute for the Study of the Atmosphere and Ocean, University of Washington, AK-40, Seattle, WA 98195.

§1. INTRODUCTION

(5) The radiance field is monochromatic and unpolarized.

The exact meaning of these assumptions and their mathematical consequences are described in the following two reports

(1) "The NHM report." This technical memorandum is the companion to the present one, and should be studied prior to reading this report. The NHM report describes the overall computational structure of the Natural Hydrosol Model and contains all the mathematical details. The full reference is

A Numerical Model for the Computation of Radiance Distributions in Natural Waters with Wind-Roughened Surfaces, by Curtis D. Mobley and Rudolph W. Preisendorfer, NOAA Tech. Memo. ERL PMEL-75, Pacific Marine Environmental Laboratory, Seattle, WA 98115, January 1988, 195 pages. (Also available from the National Technical Information Service, 5285 Port Royal Road, Springfield VA 22161, as report number PB88-192703.)

(2) "The ray-tracing report." This technical memorandum describes mathematical algorithms for simulating random air-water surfaces and for tracing light rays as the rays interact with the simulated water surface. This ray-tracing procedure is used in computing the surface boundary conditions for the radiance computations (cf. assumption 2, above). The full reference is

Unpolarized Irradiance Reflectances and Glitter Patterns of Random Capillary Waves on Lakes and Seas, by Monte Carlo Simulation, by Rudolph W. Preisendorfer and Curtis D. Mobley, NOAA Tech. Memo. ERL PMEL-63, Pacific Marine Environmental Laboratory, Seattle, WA 98115, Sept. 1985, 141 pages. (Available from NTIS as report number PB86-123577.)

Comments throughout the computer code and in the descriptive sections of this report make frequent reference to the NHM report (reference 1, just cited), enabling the user of the code to trace in detail the implementation of the mathematical procedures. Thus, in the computer code, the comment "compute forward scattering by 11.7" refers to equation 11.7 in report ERL PMEL-75. Comments referring to the ray-tracing report, ERL PMEL-63, are prefaced by "63/ ". Thus a reference to "63/3.20" refers to equation 3.20 in the ray-tracing report. To avoid confusion in the present report, references to the NHM report, ERL PMEL-75, are prefaced by "75/ ".

The various computations performed by the NHM are grouped into five separate programs, which are run in sequence to obtain the solution of a given problem. The first three programs compute the surface boundary reflectance and transmittance functions. The fourth program solves for the radiance amplitudes at all depths, and the fifth program then reconstitutes the radiances and analyzes the results. A sixth set of programs for graphical analysis of the numerical results is included for convenience although, strictly speaking, these programs are not a part of the NHM.

The following six sections of this report describe in turn the NHM programs. Each section begins with a brief description of the program. Then there are sections on the user-supplied input required to run the program, and on file management. Each program consists of a main program

§1. INTRODUCTION

named MAIN, which controls overall program flow, and a subroutine named INISHL, which reads the user-supplied data and performs other initialization tasks. The reader wishing to see the actual statements that read the user-supplied input can always find them in subroutine INISHL. Each section ends with a listing of MAIN, INISHL, and then the other subroutines of that program in alphabetical order. There are several subroutines (e.g. utility routines for printing arrays) which are used in two or more of the NHM programs. These are listed with the program in which they are first used.

The numerical computations make frequent use of the IMSL library (9th edition)¹ of FORTRAN-callable subroutines. These subroutines are used to perform standard mathematical operations such as random number generation, matrix inversion, and solving ordinary differential equations. The IMSL library is likely to be available at any scientific computing center. However, any comparable mathematical software library, such as NAGLIB², could be used after minor rewriting of the code. Appendix A lists the required IMSL subroutines. The graphics routines use standard "CalComp Basic Software"³ for plotting data.

2. PROGRAM 1

A. Program Description

This program does the ray tracing described in 75/§9a and charted in 75/Fig. 9 (i.e. in §9a and Fig. 9 of the NHM report).

It is convenient to run the program twice. The first run is used to generate and save a file of random air-water surfaces: no ray tracing is performed. The second run then reads the file of surface realizations and performs the ray tracing. This two-step procedure allows the same set of realized surfaces to be repeatedly used in the ray tracing, as follows. Each initial ray directed toward a particular input quad Q_{rs} requires an independent realization of the random water surface. However, the rays directed toward different input quads Q_{rs} and Q_{pq} can use the same set of surface realizations. Moreover, the symmetry of the water surface *for capillary waves* (see 75/§3f and 75/Fig. 5) allows a given surface realization to be rotated by $\phi = 180^\circ$ in order to get another independent surface realization. One can also turn a capillary wave surface "upside down" and get yet another independent surface realization. Thus each generated and stored capillary-wave surface can be used four times: two azimuthal orientations, each "right side up" or "upside down." The code, as listed in this report (see statements 55 to 506 in the MAIN program), makes use of these symmetries so that if, say, 10000 rays are to be traced for each input quad, only 2500 surfaces need be generated and saved in the first run. Note, however, that if a gravity-wave spectrum is used, one can no longer turn the surface upside down and get a new gravity-wave surface realization. And if the wave spectrum has different wave-slope statistics in the downwind and upwind directions, then one cannot rotate the surface by $\phi = 180^\circ$. Thus for a fully realistic, mixed gravity-capillary wave spectrum, one must generate 10000 surface realizations if 10000 rays are to be traced for each input quad Q_{rs} . However, these surface realizations (which can be very expensive to generate for a mixed gravity-capillary wave spectrum) can still be recycled for different input quads.

The net result of Program 1 is then to repeatedly obtain a random surface realization, randomly select a direction in Q_{rs} , and send a parent ray toward Q_{rs} and the realized surface. All the reflected and refracted daughter rays are traced to completion, and the quads receiving the final daughter rays are determined. One parent ray is sent toward each quad Q_{rs} in the first quadrant (of the wind-based system shown in 75/Fig. 1) for each surface realization, until the desired number of surface realizations has been made. For each (parent ray)-(daughter ray) pair, the program records the values of r , s , u , v , and the radiant flux of the daughter ray (u, v labels the output quad Q_{uv} receiving the final daughter ray). These ray-tracing computations can form a significant part of the entire work of the NHM.

Two versions of MAIN and INISHL are included in the code listing for Programs 1 and 2. The regular version of these two routines (listed first) automatically loops over all first-quadrant input quads Q_{rs} , sending rays toward each quad in turn (but using the same surface realizations

§2. PROGRAM 1

for each quad, as noted above), and thereby generating all the ray data required to compute the entire quad-averaged geometric reflectance and transmittance arrays. This version of Program 1 is to be used for production runs.

The second version of MAIN and INISHL (listed last) is a "one-quad" version, which sends rays toward only one input quad selected by the user (in the one-quad version of record 2, below). The ray data so generated lead to the evaluation of only one row of the reflectance and transmittance arrays. If the rays are air-incident, one row of $\underline{r}(a,x)$ and $\underline{t}(a,x)$ is computed; if the rays are water-incident, one row of $\underline{r}(x,a)$ and $\underline{t}(x,a)$ is computed.

The one-quad versions of Programs 1 and 2 are useful for determining how many rays must be traced to achieve a given accuracy in the elements of the quad-averaged \underline{r} and \underline{t} arrays, for a given quad resolution and wind speed. This determination must be empirically made, and the individual elements of the $f(r,s|u,v)$ arrays approach their final values at differing rates as more and more rays are tabulated. (Here $f(r,s|u,v)$ represents $r(a,x; r,s|u,v)$, or any of the other three r and t arrays.) For a given input quad Q_{rs} , the output quads Q_{uv} which are near the specular (still water) reflection or refraction directions of the parent rays in Q_{rs} will receive far more reflected or transmitted daughter rays than those quads which are in directions far from the specular directions. Thus after only a few hundred surface realizations, some elements of $f(r,s|u,v)$ may have achieved their final values with great accuracy, whereas other elements may not have had a single ray path connect the particular Q_{rs} and Q_{uv} quads. However, those elements which are largest in magnitude dominate the behavior of the light field in the sea, so it is not necessary to know all matrix elements to the same degree of accuracy. The user of the NHM is thus faced with making a decision regarding the desired accuracy of the elements of the \underline{r} and \underline{t} arrays. The larger matrix elements can and must be determined with great accuracy, but the smaller matrix elements, which are many orders of magnitude smaller than the larger elements, cannot be accurately estimated unless a tremendously large number of rays is traced.

Thus, using the one-quad version, one can make a series of runs with, say, 1000, 5000 and 10000 air-incident rays being traced for a particular input quad Q_{rs} . The computed values of $r(a,x; r,s|u,v)$ and $t(a,x; r,s|u,v)$ ($u = 1, \dots, m$ and $v = 1, \dots, 2n$) can then be studied to see how quickly these array elements achieve stable values.

Other specialized studies can be economically performed with the one-quad version. For example, for a fixed number of rays incident on the surface toward a given quad Q_{rs} , one can study the effects of wind speed on the directions of the reflected and refracted rays, and so on.

B. Input

Four parameters, which determine maximum array dimensions, must be set at compilation time. These parameters are (in the first PARAMETER statement in the MAIN program)

§2. PROGRAM 1

<u>parameter</u>	<u>value in listed code</u>	<u>definition</u>
MXMU	10	the maximum number of quads in the μ -direction in a hemisphere, including the polar cap
MXPHI	24	the maximum number of quads in the ϕ -direction, $0 \leq \phi \leq 2\pi$
MXSTAK	10	the maximum number of rays in the push-pull stack at once
MXNHEX	7	the maximum order of the hexagonal grid used for ray tracing

Referring to 75/§3a, MXMU gives the maximum allowed value of m (\equiv NMU, below), and MXPHI gives the maximum value of N (\equiv NPHI, below). Figures 75/4a, 75/4b and 75/4d show quad partitions for which $m = 10$ and $N = 24$. A run using the quad partitioning of 75/Fig. 4c has $m = 23$ and $N = 60$, as so would require $MXMU \geq 23$ and $MXPHI \geq 60$. For efficient use of computer storage, one should pick MXMU and MXPHI to be the same as the actual number of μ and ϕ cells in the quad partitioning, NMU and NPHI, respectively, to be specified in record 2, below. The value of $MXSTAK = 10$ should be sufficient for any problem (see 63/page 11, i.e. page 11 in the ray-tracing report). $MXNHEX = 7$ is sufficient for simulation of capillary wave surfaces. 75/Fig. 8 and 63/Fig. 5 each show hexagonal grids of order two ($NHEX = 2$). Proper resolution of mixed gravity-capillary waves requires high-order hexagonal grids ($NHEX$ of 100 or more), and so $MXNHEX$ must be increased accordingly if such studies are to be made.

Two or three free-format data records are read at execution time (see subroutine INISHL). In essence, the first record specifies the water surface; the second (and optional third) specifies the quad partitioning and the number of rays to be traced. The records are as follows:

Record 1: IDBUG, IGENSF, NHEX, WNDSPD, DSEED

IDBUG	= 0	for minimal output (production runs)
	= 1	for greater output
	= 2	for full debugging output
IGENSF	= 0	if a file of random surfaces already exists, and is to be used for ray tracing
	> 0	if this is an initial run for generating and saving a file of random surfaces. The value of IGENSF gives the number of surfaces to be generated (IGENSF = 2500, say).
NHEX		gives the order of the hexagonal surface grid ($NHEX = 7$ is adequate for capillary waves).

§2. PROGRAM 1

- WINDSPD gives the wind speed for use in the wave spectrum, e.g. WINDSPD = 10.0 for a 10 m s^{-1} wind at 12.5 m elevation (see 63/page 15).
- DSEED is a double precision seed for the IMSL random number generators, e.g. DSEED = 18762203.D0

If IGENSF > 0, only record 1 is required.

Record 2: NMU, NPHI, MUPART, NREAD0, NUMRAY

- NMU gives the number of μ -cells in one hemisphere in the quad partitioning (the value of m on 75/page 20).
- NPHI gives the number of ϕ -cells in the quad partitioning (the value of N on 75/page 20). NPHI must be a multiple of 4.
- MUPART selects the scheme for μ -partitioning of the unit sphere (see 75/page 22-24), as follows:
- = 1 if all quads are to have equal solid angles
 - = 2 if all quads are to have equal $\Delta\theta$ values
- The user may write subroutines to define other quad partitions, using other values of this variable to select the desired subroutine.
- NREAD0 = 1 if the file of stored surface realizations is to be read from the start (the usual case)
= 2, 3 or 0 if the file is to be read starting with a rotation or inversion of the stored surfaces (this can be useful if additional rays are to be traced and complete use of the stored surfaces has not yet been made)
- NUMRAY gives the number of rays to be traced from each input quad
- if NUMRAY < 0, then a third record is used to give the number of rays to be traced from quads in each μ -band.

Record 2a: NRAYQD(1), ..., NRAYQD (NMU)

This record is read only if NUMRAY < 0 in record 2.

- NRAYQD(1) gives the number of rays to be traced from each input quad in the μ -band nearest the equator ($r = 1$), and so on until
- NRAYQD(NMU) gives the number of rays to be traced from the polar cap ($r = m = \text{NMU}$)

Record 2a can be used if, for example, one wants to trace a certain number of initial rays per steradian, but the quads have different solid angles in the various μ -bands. Or, if it is found in preliminary studies (e.g. with the one-quad version) that more rays must be traced from quads

§2. PROGRAM 1

near the equator than from quads near the polar caps, in order to achieve the desired accuracy, then record 2a must be used.

Record 2, one-quad version: NMU, NPHI, MUPART, IR, JS, NUMRAY

NMU, NPHI, MUPART and NUMRAY are as above. IR and JS give the values of r and s , respectively, specifying the input quad Q_{rs} . If IR is positive, $1 \leq IR \leq NMU$, the rays are air-incident. If IR is negative, $-NMU \leq IR \leq -1$, the rays are water-incident. JS must be in the first quadrant, i.e. $1 \leq JS \leq NPHI/4+1$.

C. File Management

Throughout the NHM, files are given a symbolic (alphanumeric) filename beginning with "NU" (e.g. NUSFC for the file containing the surface realizations), as well as an external filename of the form "TAPEXX", where XX is a FORTRAN logical unit number (e.g. TAPE15 is the file NUSFC). This naming scheme is appropriate for CDC computers, but may require minor modification on other machines. User-supplied input is always read from unit 5 (INPUT, or TAPE5) and printout is written to unit 6 (OUTPUT, or TAPE6), in accordance with standard FORTRAN conventions.

Program 1 creates the following five files:

<u>symbolic filename</u>	<u>external filename</u>	<u>description</u>
NUSFC	TAPE15	the file of random surface realizations; created in the initial run of Program 1, and read in the ray-tracing run of Program 1
NUDU	TAPE16	a ray-data file, containing initial and final ray direction and radiance information, for initial rays <u>downward</u> and final rays <u>upward</u> . Created in the second run of Program 1 and used to compute $r(a,x; r,slu,v)$
NUDD	TAPE17	ray data file for initial rays <u>downward</u> , final rays <u>downward</u> ; used to compute $t(a,x; r,slu,v)$
NUUD	TAPE18	ray data file for initial rays <u>upward</u> , final rays <u>downward</u> ; used to compute $r(x,a; r,slu,v)$
NUUU	TAPE19	ray data file for initial rays <u>upward</u> , final rays <u>upward</u> ; used to compute $t(x,a; r,slu,v)$

Program 2 reads the four ray-data files and tallies the information to generate the quad-averaged, geometric reflectance and transmittance arrays.

3. PROGRAM 2

A. Program Description

This program tallies the ray information from Program 1 and computes the four quad-averaged geometric reflectance and transmittance arrays, using 75/9.1a-d and 75/9.7a-d. Once again, there is an "all-quad" and a "one-quad" version of Program 2, to be run with the ray-data files of the corresponding versions of Program 1.

Program 1 creates all four ray-data files (Tapes 16, 17, 18 and 19) in one run. Program 2 processes these files one at a time, in four separate runs, generating four separate output files.

After running Programs 1 and 2 and studying the resultant quad-averaged geometric r and t arrays, the user may decide that still more rays should be traced in order to increase the accuracy of the computed array elements. In this case, Program 1 can be run again to generate a new batch of rays. Program 2 can then read the new ray-data files from Program 1, read the output files from the *previous* run of Program 2, and merge the new and old information to create an updated set of r and t arrays. This repetition of Program 1 and 2 can be repeated until a satisfactory number of rays has been traced and the r and t array elements have been declared sufficiently accurate.

B. Input

Only one free-format data record is required:

Record 1: NEWRUN, IDBUG

NEWRUN = 1 if this is the first run of Program 2
 = 0 if Program 2 has already been run, and new ray data are to be merged with existing r and t files from the previous run of Program 2

IDBUG = 0, 1 or 2, as in record 1 of Program 1

C. File Management

File management for Program 2 depends on whether this is an initial run (NEWRUN = 1) or a continuation run to incorporate additional ray data (NEWRUN = 0). In either case, four separate runs must be made in order to process the four output ray-data files from Program 1. The file names are as follows:

Initial run (NEWRUN = 1)

There is one input file, always named TAPE20. This file is either of TAPE16, TAPE17, TAPE18 or TAPE19 from Program 1, locally renamed as TAPE20. There is one output file with symbolic filename of NUOUT. The external file name for NUOUT is

§3. PROGRAM 2

$$\left. \begin{array}{l} \text{TAPE22} \\ \text{TAPE23} \\ \text{TAPE24} \\ \text{TAPE25} \end{array} \right\} \text{ if TAPE20 is } \left. \begin{array}{l} \text{TAPE16} \\ \text{TAPE17} \\ \text{TAPE18} \\ \text{TAPE19} \end{array} \right\}.$$

These external filenames are generated automatically by Program 2. The user should save NUOUT with an appropriate descriptive filename, to avoid confusion if more than one set of runs of Programs 1 and 2 is made.

Continuation run (NEWRUN = 0)

There are now two input files, always named TAPE20 and TAPE21. As above, TAPE20 is either of TAPE16,...,TAPE19 containing *new* ray data from a second run of Program 1. TAPE21 is the corresponding output file from the *previous* run of Program 2, i.e. TAPE21 is the renamed TAPE22,...,TAPE25 from the previous run. The output file, NUOUT, is corresponding TAPE22,...,TAPE25 and contains the updated r or t array. In other words,

$$\text{if TAPE20 is the new } \left. \begin{array}{l} \text{TAPE16} \\ \text{TAPE17} \\ \text{TAPE18} \\ \text{TAPE19} \end{array} \right\}, \text{ then TAPE21 is } \left. \begin{array}{l} \text{TAPE22} \\ \text{TAPE23} \\ \text{TAPE24} \\ \text{TAPE25} \end{array} \right\} \text{ from the previous run,}$$

$$\text{and NUOUT is the updated } \left. \begin{array}{l} \text{TAPE22} \\ \text{TAPE23} \\ \text{TAPE24} \\ \text{TAPE25} \end{array} \right\}.$$

The most convenient manner for keeping track of these files, if multiple runs of Programs 1 and 2 are made, depends on the particular computer system.

The final versions of TAPE22,...,TAPE25 contain the quad-averaged geometric arrays as follows:

$$\left. \begin{array}{l} \text{TAPE22} \\ \text{TAPE23} \\ \text{TAPE24} \\ \text{TAPE25} \end{array} \right\} \text{ contains } \left. \begin{array}{l} \underline{r(a,x)} \\ \underline{t(a,x)} \\ \underline{r(x,a)} \\ \underline{t(x,a)} \end{array} \right\}.$$

All four of these files are read by Program 3. TAPE22 ($\underline{r(a,x)}$) and TAPE25 ($\underline{t(x,a)}$) also are read by Program 5, if the contrast transmittance is computed.

4. PROGRAM 3

A. Program Description

This program reads the four quad-averaged *geometric* reflectance and transmittance arrays computed by Program 2 ($\underline{r}(a,x)$ on TAPE22, etc.). The corresponding *spectral* arrays $\hat{r}_1(a,x)$, $\hat{r}_2(a,x)$, etc. are computed using 75/5.31c, 75/5.32, 75/5.34, and 75/5.36. All arrays are processed in one run of Program 3.

Recall that Programs 1, 2 and 3 are concerned only with the air-water surface boundary conditions. We have so far specified only the quad partitioning and the wind speed. The surface boundary condition computations are thus completely independent of the inherent optical properties of the water body, of the incident lighting, etc. (all to be specified in Program 4). The output from Program 3 can therefore be run with many different versions of Program 4, i.e. with many different water bodies. Only a few runs of Programs 1-3 are necessary (say at two or three different wind speeds) in order to study a wide range of ocean optics problems in which the water type, bottom boundary condition, or incident lighting are varied.

B. Input

Only one user-supplied input record is required:

Record 1: IDBUG

where IDBUG = 0,1, or 2 as in Program 1.

C. File Management

Program 3 reads the four output files from Program 2 and creates one output file, as follows:

<u>symbolic name</u>	<u>external name</u>	<u>description</u>
NURAX	TAPE22	the quad-averaged geometric $\underline{r}(a,x)$ array
NUTAX	TAPE23	the $\underline{t}(a,x)$ array
NURXA	TAPE24	the $\underline{r}(x,a)$ array
NUTXA	TAPE25	the $\underline{t}(x,a)$ array
NUOUT	TAPE30	the four spectral \hat{r} and \hat{t} arrays, written in the order in which they are needed in Program 4, namely $\underline{t}(a,x)$, $\hat{r}(x,a)$, $\underline{t}(x,a)$, and $\hat{r}(a,x)$

TAPE30 contains all of the surface boundary condition information needed by Program 4.

5. PROGRAM 4

A. Program Description

This program performs the remaining initialization steps of 75/7a.3-7a.5 and then assembles the solution amplitudes as described in 75/§7b. The internal structure of Program 4 is essentially that shown in 75/Fig. 7. This program is the other main consumer of computer power in the NHM, owing to the discretization of the phase function.

It is usually convenient to run Program 4 in two different modes. In the first mode (ICPHAS $\neq 0$ in record 3, below), the program computes and stores the quad-averaged phase function as described in 75/§11. These calculations can be very expensive if the phase function is highly peaked in the forward direction, as is the case in natural waters. However, these calculations need be done only once for a given phase function (and a given quad partition). In the second mode (ICPHAS = 0 in record 3), it is assumed that the phase function has already been discretized; the file containing this information is read and the radiance amplitudes are then computed. In the case of a spherically symmetric phase function, which may be of interest for comparison purposes, the discretization calculations are trivial. In this case, it may be convenient to run Program 4 to completion each time (i.e. both modes 1 and 2); the discretized spherical phase function is not worth saving.

B. Input

Two more parameters, which determine maximum array dimensions, must be set at compilation time. These parameters are (see the first PARAMETER statement in MAIN).

<u>parameter</u>	<u>value in listed code</u>	<u>definition</u>
MX Y	30	the maximum number of optical depths y_j , $j = 1, \dots, YOUT$, at which the final output is desired (see 75/Fig. 6)
MXSIG Y	3	the maximum number of optical depths y_i , $i = 1, \dots, YOP$, at which the inherent optical properties are specified (see 75/Fig. 6)

Referring to 75/pages 132-135, MX Y gives the maximum allowed value of YOUT and MXSIG Y gives the maximum allowed value of YOP.

Six free-format data records are read at execution time, as follows.

Record 1: ITITLE

This is an alphanumeric title for the run, used to identify the printout. Up to 80 characters are allowed.

§5. PROGRAM 4

Record 2: IDBUG, WAVENM, ABSORB

IDBUG = 0, 1, or 2, as in Program 1

WAVENM is the wavelength in nanometers of the monochromatic radiance. This wavelength is used in subroutine PHASEF (see the version for the Pelagos Sea in the code listing) to select the correct wavelength dependent absorption and scattering functions. In the listed code, WAVENM *must* be one of the 13 wavelengths 400.0, 425.0, ..., 675.0, 700.0, although this is not a restriction of the NHM algorithms.

ABSORB If ABSORB < 0.0, then the value of the absorption coefficient returned by PHASEF is used. If ABSORB ≥ 0.0, then the absorption coefficient is set to ABSORB. This overrides the value returned by PHASEF. (This is useful for studies in which only the scattering-to-absorption ratio changes.)

Record 3: ICPHAS, NUQB, NVQB, INCBAS

This record gives information for the discretization of the phase function.

ICPHAS = 0 if the phase function has already been discretized in a previous run of Program 4. File NUPHAS will be read.

≠ 0 if this run is to discretize the phase function. If ICPHAS < 0, the run stops after file NUPHAS has been written. If ICPHAS > 0, the run discretizes the phase function, writes file NUPHAS, and continues with the amplitude computations.

NUQB the value of n_{μ} in 75/11.3. A value of 1 can be used for a spherically symmetric phase function. Use NUQB = 3 or 4 for the quad resolution of 75/Fig. 4a or 4b and phase functions typical of natural waters.

NVQB the value of n_{ϕ} in 75/11.3. Use values like those for NUQB.

INCBAS the factor for increasing the base numbers of subcells (n_{μ} and n_{ϕ}) in 75/11.3, for quad pairs which involve forward (or near forward) scattering. A value of 10 is reasonable for natural waters (use 1 if the phase function is spherically symmetric). If NUQB = 3 and INCBAS = 10, say, then in 75/11.3, n_{μ} is increased to 30 for quads involving forward scattering. This gives a more accurate evaluation of 75/11.1.

Record 4: IBOTM, RFLBOT

This record specifies the bottom boundary condition.

IBOTM = 0 if the bottom is to be a matte surface at a finite depth. The surface has a reflectance of $r_{-} = RFLBOT$ (see 75/3.26)

§5. PROGRAM 4

= 1 if the bottom is infinitely deep, and the water is homogeneous below depth z (see 75/§10).

RFLBOT The bottom reflectance (used only if IBOTM = 0). $0.0 \leq \text{RFLBOT} \leq 1.0$.

Record 5: IYOP, NY, YOUT(1),...,YOUT(NY)

This record specifies the depths at which output is desired.

IYOP = 0 if the YOUT values as read are geometric depths in meters (in the listed code, this option is available only for attenuation functions which are independent of depth).
 = 1 if the YOUT values as read are optical depths (this option is valid for inhomogeneous waters).

NY the number of y-levels where output is required (NY is YOUT in 75/Fig. 6. $\text{NY} \leq \text{MXY}$).

YOUT(1)
 ⋮
 YOUT(NY) the depths where output is desired. Always set $\text{YOUT}(1) = 0.0 \equiv x$. The value of $\text{YOUT}(\text{NY})$ is z (see 75/Fig. 6).

A convenient set of optical depths for printout in infinitely deep water, homogeneous below $z = 20.0$ optical depths, might be

0.0, 0.5, 1.0, 2.0, 5.0, 10.0, 15.0, and 20.0.

Here: $\text{YOUT}(1) \equiv x = 0.0$, $\text{YOUT}(2) = 0.5, \dots, \text{YOUT}(\text{NY}) \equiv z = 20.0$, with $\text{NY} = 8$. See input records 3 and 5 of Program 5 for special choices of $y_j = \text{YOUT}(j)$ which are often convenient for checking the results, computing K-functions, etc.

Record 6: RSKY, CARD, SHTOTL, THETAS, PHIS

This record specifies the incident (sky + sun) radiance distribution, using the model described in Appendix B.

RSKY The ratio of sky to total (sky + sun) input scalar irradiance; $0.0 \leq \text{RSKY} \leq 1.0$. $\text{RSKY} = 0.0$ for a black sky (sun only); $\text{RSKY} = 1.0$ for a background sky only (no sun).

CARD The cardioidal parameter for the sky radiance distribution (see Appendix B of this report): $\text{CARD} = 0.0$ for a uniform sky; $\text{CARD} = 2.0$ for a cardioidal sky.

SHTOTL The total (sky + sun) spectral scalar irradiance on the water surface at the given wavelength, in $\text{W m}^{-2} \text{nm}^{-1}$.

THETAS The polar angle, θ_s , in degrees of the sun's location in the sky. $\text{THETAS} = 0.0$ for the sun at the zenith; $\text{THETAS} = 90.0$ for the sun at the horizon.

§5. PROGRAM 4

PHIS The azimuthal angle, ϕ_s , in degrees of the sun's location, measured counterclockwise from $\phi_s = 0.0$ in the downwind direction (e.g. PHIS = 90.0 places the sun in the crosswind direction).

In addition to the above data records, the user must make sure that the desired version of subroutine PHASEF is being used. This routine specifies the inherent optical properties of the water body. Four versions of PHASEF are listed in this report. Two of these define absorption and scattering functions typical of natural waters: "Lake Limne" and "the Pelagos Sea" which are, respectively, typical of lakes and open ocean waters. The other two examples of PHASEF are for a spherical scattering function: one is depth independent and one is for depth dependent absorption and scattering. The user wishing to make runs with his own absorption and scattering functions must write a corresponding version of PHASEF, mimicking the listed examples.

Likewise, a user wishing to specify an input radiance distribution other than the ones obtainable from the formulas in Appendix B must write a corresponding version of subroutine QASKY. This would be the case if, for example, the user had measured the sky radiance distribution with a few cumulus clouds present in an otherwise clear sky, and wished to include the cloud effects in the computed radiances.

C. File Management

Three permanent files are either read or written by Program 4; an additional three temporary files are used for scratch storage.

<u>internal name</u>	<u>external name</u>	<u>description</u>
NUSRT	TAPE30	The file of spectral \hat{r} and \hat{t} arrays for the air-water surface, from Program 3.
NUPHAS	TAPE39	The file containing the quad-averaged phase function. It is written if ICPHAS \neq 0 and read if ICPHAS = 0.
NUOUT	TAPE40	The file containing the radiance amplitudes (and other information) generated by Program 4.
NUSCR1	TAPE45	Temporary scratch files used in integrating the Riccati equations. NUSCR1 holds $R(y,x;\ell)$; NUSCR2 holds $T(x,y;\ell)$; NUSCR3 holds $R_1(y,b;\ell)$ and $R_2(y,b;\ell)$.
NUSCR2	TAPE46	
NUSCR3	TAPE47

C
DATA NUSRT,NUPHAS,NUOUT/30,39,40/
KINV.....THE NUMBER OF TERMS IN THE SUM (7.4)
TOL.....THE TOLERANCE FOR THE RICCATI EQUATION SOLVER (IMSL ROUTINE DVERK)
DATA KINV/3/, TOL/1.0E-8/
C
READ INPUT RECORDS
C
RECORD 1:
C ITITLE....A RUN TITLE, UP TO 80 CHARACTERS
C
RECORD 2:
C IDBUG.....0 FOR NO INTERMEDIATE OUTPUT (PRODUCTION RUNS)
C           1 FOR MINIMAL OUTPUT FOR CHECKING (RECOMMENDED)
C           2 FOR FULL DEBUGGING OUTPUT
C WAVENM....THE WAVELENGTH IN NANOMETERS, ONE OF THE 13 VALUES 400.,425.,.....,
C           675.,700. (SEE PHASEF FOR THE PELAGOS SEA)
C ABSORB....IF.GE.0., THEN THE ABSORPTION COEF A IS RESET TO THIS VALUE
C           (USED FOR LAKE LIMNE RUNS TO VARY A WITH WAVELENGTH)
C
RECORD 3:
C ICPHAS....0 IF THE QUAD-AVERAGED PHASE FUNCTIONS ARE TO BE READ
C           FROM UNIT NUPHAS
C           .NE.0 IF THE QUAD-AVERAGED PHASE FUNCTIONS ARE TO BE COMPUTED
C           (BY SUBROUTINE QPHAS) AND STORED ON UNIT NUPHAS
C           IF ICPHAS.LT.0, THE RUN STOPS AFTER NUPHAS IS WRITTEN
C           IF ICPHAS.GT.0, THE RUN CONTINUES, AND COMPUTES
C           AMPLITUDES
C NUQB,NVQB.THE BASE NUMBERS OF SUBCELLS (IN THE MU AND PHI DIRECTIONS)
C           USED TO DISCRETIZE THE PHASE FUNCTION VIA EQ. 11.3
C           (USED ONLY IF ICPHAS.NE.0)
C INCBAS....THE FACTOR FOR INCREASING THE BASE NUMBER OF SUBCELLS
C           FOR QUAD PAIRS WHICH INCLUDE FORWARD SCATTERING
C
RECORD 4:
C IBOTM....0 FOR A MATTE BOTTOM AT Y = Z, OF REFLECTANCE R- = RFLBOT
C           1 FOR AN INFINITELY DEEP BOTTOM, WITH HOMOGENEOUS WATER
C           BELOW DEPTH Y = Z
C RFLBOT....THE BOTTOM REFLECTANCE, (USED ONLY IF IBOTM = 0)
C           0.0 .LE. RFLBOT .LE. 1.0
C
RECORD 5:
C IYOP.....0 IF YOUT AS READ CONTAINS GEOMETRIC DEPTHS IN METERS
C           (USE FOR UNIFORM WATER ONLY, AS OF 30 JUNE 86)
C           1 IF YOUT AS READ CONTAINS OPTICAL DEPTHS
C NY.....THE NUMBER OF Y LEVELS WHERE OUTPUT IS DESIRED
C YOUT(1),...,YOUT(NY)...THE DEPTHS WHERE OUTPUT IS DESIRED
C
RECORD 6:
C RSKY.....THE RATIO OF SKY TO TOTAL INPUT SCALAR IRRADIANCE
C           RSKY = 0. FOR A BLACK SKY (SUN ONLY), RSKY = 1.0 FOR A
C           BACKGROUND SKY ONLY (NO SUN)

C
C   N.B.: THE REQUESTED WAVELENGTH, WAVENM, SHOULD BE ONE OF THE
C   DISCRETE NHM WAVELENGTHS (NAMELY, 400., 425., ..., 675. OR 700. NM).
C   THIS IS BECAUSE THE SIGMA(90) VALUES CANNOT BE OBTAINED BY
C   INTERPOLATION OF THE TABULATED VALUES.
C
C   SINCE THE PHASE FUNCTION IS NEARLY LINEAR ON A LOG-LOG PLOT,
C   LINEAR INTERPOLATION IS PERFORMED IN LOG(PHASE)-LOG(PHI) IN ORDER
C   TO DEFINE VALUES OF THE PHASE FUNCTION AT ARBITRARY PHI VALUES.

6. PROGRAM 5

A. Program Description

This program first synthesizes the radiances from the amplitudes found in Program 4. Then the results are analyzed and derived quantities are computed, as detailed in 75/§8. Multiple runs of Program 5 can be made for a given set of output from Program 4. For example, one run can be made to check the balance of the radiative transfer equation, another run to compute the irradiances and other derived quantities, etc.

We note again, as discussed in 75/§7a, that the expensive computations for the quad-averaged upper boundary r and t arrays need be done only once for a given wind speed and quad resolution. Likewise, the expensive discretization of the phase function is a one-time computation for a given phase function. The actual solution of the radiative transfer equation in Programs 4 and 5 is relatively inexpensive. Therefore, holding the wind speed and phase function fixed, it is possible to make many runs of Programs 4 and 5 in order to study the effects of varying the incident radiance distribution, the scattering-to-absorption ratio $s/a = \omega/(1-\omega)$, the bottom boundary type, etc. It is often convenient to make a run of Programs 4 and 5 with radiance output (see record 5 of Program 4 and records 2, 4 and 5, below) at some standard set of depths, say at y values of 0.0, 0.5, 1.0, 2.0, 5.0, 10.0, and 20.0 optical depths (here $YOUT(1) \equiv x = 0.0$ and $YOUT(NY) \equiv z = 20.0$, with $NY = 7$). If inspection of this run indicates a "region of interest" (e.g. large changes in the radiance field with depth, or "kinks" in the K -function curves) between $y = 2.0$ and $y = 5.0$, say, then another run of Programs 4 and 5 can be made to give greater resolution in the region of interest. The second run could save the output at y values of 0.0, 1.0, 2.0, 2.5, 3.0, 3.5, 4.0, 4.5, 5.0, 10.0 and 20.0 (now $NY = 11$).

In addition to the specific analyses selected by the input records below, a basic "skeleton" of radiance values is always printed (e.g. upward, downward and horizontal radiances in the alongwind and crosswind directions at selected depths, cf. subroutine RADY).

Other useful quantities automatically computed and printed are the contrast transmittance (cf. 75/§8k and subroutine CONTRM), and the backward and forward scattering functions (cf. 75/§8d and subroutine BFSCAT). If desired, this output can be removed by deleting the calls to the appropriate subroutines.

Additional output is included where convenient in many of the subroutines. For example, path functions (cf. 75/§8g) are computed along with the radiance K -functions (subroutine KRAD). Distribution functions (75/8.11) and reflectance functions (75/8.14) are computed along with the irradiances (subroutine IRRAD). Eccentricities (75/8.16b) are included with the backward and forward scattering functions.

B. Input

From five to nine free-format records are read to specify the type of analysis desired.

§6. PROGRAM 5

Record 1: ITITLE

This is an alphanumeric title for the run, used to identify the printout. Up to 80 characters are allowed.

Record 2: IPRAD, IPRAD1, IPRAD2, IPRAD3, JPRAD1, JPRAD2, JPRAD3

This record (along with record 2a, if required) specifies the extent of printout of the radiance distribution by subroutine PRINT.

IPRAD < 0 if a printout of the radiance distribution is desired at *every* y level where the radiance was computed: $y = a, YOUT(1) = x, \dots, YOUT(NY) = z$

IPRAD = 0 if *no* printout of the radiances is desired

IPRAD > 0 if printout is desired only at certain y levels, IPRAD in number, to be specified in record 2a

IPRAD1,
IPRAD2,
IPRAD3 are DO-LOOP indices of the form
DO 302 I=IPRAD1, IPRAD2, IPRAD3
which select the μ -bands of quads for which printout is desired. For example, consider the $m = 10$ by $2n = 24$ quad partition of 75/Fig. 4a. There are $m = 10$ μ -bands in each hemisphere ($\mu_u, u = 1, \dots, m$). If $(IPRAD1, IPRAD2, IPRAD3) = (1, 10, 1)$ then all μ -bands will be printed. If $(IPRAD1, IPRAD2, IPRAD3) = (1, 10, 3)$ then only bands $u = 1, 4, 7$ and 10 are printed out (the polar cap values, $u = m$, are always printed). See DO-LOOPS 302 and 103 in subrouting PRINT (where index I is u).

JPRAD1,
JPRAD2,
JPRAD3 are DO-LOOP indices which select the ϕ -bands to be printed, $\phi_v, v = 1, \dots, 2n$. Referring again to 75/Fig. 4a, if $(JPRAD1, JPRAD2, JPRAD3) = (1, 24, 1)$ then all ϕ -bands would be printed. If $(JPRAD1, JPRAD2, JPRAD3) = (1, 24, 6)$ then only the ϕ -bands at $v = 1, 7, 13, 19$ (corresponding to $\phi = 0^\circ, 90^\circ, 180^\circ, 270^\circ$ in 75/Fig. 4a) are printed. See DO-LOOPS 302 and 103 in PRINT (where index J is v).

Record 2a: IYPRAD(1), ..., IYPRAD(IPRAD)

This record is read only if IPRAD > 0. The values of IYPRAD are the j indices of $y_j, j = 1, \dots, YOUT$, at which printout is desired. (See 75/Fig. 6 and input record 5 of Program 4, where y_j is YOUT(J).)

Record 3: IRTECK, NIC, NJC

This record specifies whether or not the balance of the radiative transfer equation (RTE) is to be checked; see 75/§8a and pay special attention to 75/8.3 and the requirement of closely spaced y_j values.

§6. PROGRAM 5

- IRTECK < 0 if the balance of the RTE is to be computed at all possible interior y-levels, YOUT(2),...,YOUT(NY-1)
- IRTECK = 0 if no RTE balance check is to be made
- IRTECK > 0 if record 3a gives the indices of the y-levels where the RTE check is to be made. Normally, the RTE is checked only at the center y-level of three closely spaced y-levels (see 75/8.3). Thus if the user plans to check the RTE, foresight must be shown in specifying the y-levels in record 5 of Program 4. "Closely spaced" y-levels are separated by, say, 0.01 optical depths. Thus a choice of y-levels in record 5 of Program 4 might be 0.0, 0.99, 1.00, 1.01, 4.99, 5.00, 5.01,... The balance of the RTE could then be checked at levels 1.00 and 5.00.

NIC, NJC are DO-LOOP increments used to select particular μ and ϕ values where the RTE balance is to be checked. See DO-LOOPS 300 in subroutine RTECK, which are of the form

```
DO 300 J = 1, NPHI, NJC
DO 300 I = 1, 2*NMU, NIC
where  $\mu(I)$  is in  $\Xi_-$  if  $I \leq NMU$ 
and  $\mu(I)$  is in  $\Xi_+$  if  $NMU < I \leq 2*NMU$ 
```

Record 3a: IYRTE(1),...,IYRTE(IRTECK)

This record is read only if IRTECK > 0. IYRTE(J) is the index j in 75/8.3. It is assumed that y_{j-1} , y_j and y_{j+1} are closely spaced. Note that $IYRTE(1) \geq 2$ and $IYRTE(IRTECK) \leq NY-1$.

Record 4: IPIRAD

This record (and record 4a if required) specifies the y levels at which irradiances, distribution functions, and reflectances are printed out. (Irradiances, etc. are automatically computed at all y-levels, e.g. for use in computing K-functions, but are printed out only at desired levels.)

- IPIRAD < 0 if the irradiances, etc. are to be printed out for all y-levels
- IPIRAD = 0 if irradiances are to be printed out only at levels y_j , $j = 1, 2, 4, 6, 8, \dots$. This is convenient when YOUT (Record 5 in Program 4) has specified closely spaced *pairs* of depths, as is convenient for computing K-functions (see subroutines KFCN and KRAD)
- IPIRAD > 0 if the irradiances are to be printed out only at selected y-levels, IPIRAD in number, to be specified in record 4a

Record 4a: IYIRAD(1),...,IYIRAD(IPIRAD)

This record is read only if IPIRAD > 0. IYIRAD(j), $j = 1, \dots, IPIRAD$, are the indices of the y_j -levels whose irradiance data is to be printed out; $1 \leq IYIRAD(j) \leq NY$.

§6. PROGRAM 5

Record 5: IPKFCN, ISTART, ISTOP, ISTEP, JSTART, JSTOP, JSTEP

This record (and record 5a if required) specifies the computation and printout of K-functions for irradiance and radiance, using 75/8.12 and 75/8.26. The y-derivatives are estimated by using consecutive *pairs* of depths, i.e. $dy \doteq y_{j+1} - y_j = YOUT(j+1) - YOUT(j)$ if the K-function is requested at level j. These derivative estimates will be inaccurate if y_{j+1} and y_j are not closely spaced – say, 0.01 optical depths apart. Thus foresight must be shown when specifying output depths in record 5 of Program 4 if K-functions are to be computed.

- | | | |
|----------------------------|-----|---|
| IPKFCN | < 0 | if irradiance (and optionally radiance) K-functions are to be computed at all possible depths YOUT(1),...,YOUT(NY-1) |
| IPKFCN | = 0 | if the K-functions are to be computed at levels y_j , $j = 1, 3, 5, 7, \dots$. This is convenient if record 5 of Program 4 has selected closely spaced pairs of output depths, i.e. y_1 and y_2 are closely spaced, y_3 and y_4 are closely spaced, etc. An example of record 5 of Program 4 following this scheme is
0.0, 0.01, 0.50, 0.51, 1.00, 1.01, 2.00, 2.01, ...
One could then accurately compute K-functions at levels
0.005, 0.505, 1.005, 2.005,
by using IPKFCN = 0 |
| IPKFCN | > 0 | if K-functions are to be computed only at selected y-levels, IPKFCN in number, to be specified in record 5a |
| ISTART,
ISTOP,
ISTEP | | are DO-LOOP indices which select the μ -bands of quads for which <i>radiance</i> K-functions are to be computed, if ISTART > 0. (ISTART, ISTOP, ISTEP) are identical in form to (IPRAD1, IPRAD2, IPRAD3) in record 2. See DO-LOOP 200 in subroutine KRAD. |
| ISTART | < 0 | if radiance K-functions are <i>not</i> to be computed |
| JSTART,
JSTOP,
JSTEP | | are DO-LOOP indices which select ϕ -bands of quads for which radiance K-functions are to be computed. See (JPRAD1, JPRAD2, JPRAD3) in record 2 and DO-LOOP 200 in subroutine KRAD. |

Record 5a: IYKFCN(1),...,IYKFCN (IPKFCN)

This record is read only if IPKFCN > 0. IYKFCN(j), $j = 1, \dots, IPKFCN$, are the indices of the y_j -levels where the K-functions are to be computed; $1 \leq IYKFCN(j) \leq NY-1$.

C. File Management

Three files are read by Program 5, and one is written.

§6. PROGRAM 5

<u>symbolic name</u>	<u>external name</u>	<u>description</u>
NURAX	TAPE22	the quad-averaged geometric $\underline{r}(a,x)$ array from Program 2
NUTXA	TAPE25	the quad-averaged geometrix $\underline{t}(x,a)$ array from Program 2
NUIN	TAPE40	the radiance amplitudes and other information, generated by Program 4
NUOUT	TAPE50	a file containing discretized phase functions, radiances, and other information, for use by the graphics routines

Files NURAX and NUTXA are used only by subroutine CONTRM, which computes the contrast transmittance.

§6. PROGRAM 5

D. Code Listing

```

PROGRAM MAIN(INPUT,OUTPUT,TAPES=INPUT,TAPE6=OUTPUT,

7. GRAPHICS PROGRAMS

The running of the Natural Hydrosol Model is completed with the computations of Program 5. TAPE50, written by Program 5, contains the computed radiances and other information. However, the most convenient form for the output is often graphical. We therefore include in this report a few programs for plotting radiance distributions, chromaticity diagrams, and the like.

Each of the listed programs uses standard CalComp Basic Software, as implemented on the author's CDC Cyber 855 computer. This implementation uses both TAPE98 and TAPE99 in order to generate output files for both videoterminal and hardcopy plot devices. This is non-standard, but only minor rewriting will be required to use the programs on other computer systems.

A. Plotting Radiance Distributions

Program MPRAD reads the radiance data from TAPE50 and plots radiance distributions, as a function of depth and direction, on a variety of formats.

1. Input

Each plot is generated by two to four free-format records.

Record 1: ITYPE, NTIT, NYPLT

ITYPE		specifies the type of plot to be made, as described in record 2, below.
NTIT	≤ 0	if no title is desired at the top of the plot
	> 0	if an alphanumerical title for the top of the plot is to be read in record 1a
NYPLT	≤ 0	if all y-levels are to be plotted
	> 0	if only selected y-levels, NYPLT in number, are to be plotted, as specified in record 1b

Record 1a: ITITLE

This record is read only if ITIT > 0 . ITITLE is an alphanumeric title for the top of the plot. Up to 80 characters are allowed.

Record 1b: IYPLT(1), ..., IYPLT(NYPLT)

This record is read only if NYPLT > 0 . The values of IYPLT are the J indices of YOUT(J), $J = 1, \dots, NY$ at which plots are to be made (cf. record 5 of Program 4).

§7A. PLOTTING RADIANCES

Record 2: depends on ITYPE

This record is the *specification record*. It gives the values of the parameters needed to specify the details of the plot, as follows:

- If ITYPE = 1, make polar plots of the logarithm of the diffuse radiance as a function of θ . The specification record gives JPHI and JPI, which are the ϕ -indices of two half-planes. Normally $\phi(JPI) = \phi(JPHI) + \pi$, so that a planar cross section of the radiance is plotted. A separate plot is made for each depth.
- If ITYPE = 2, make polar plots of the logarithm of the total radiance as a function of θ . Otherwise as for ITYPE = 1.
- If ITYPE = 3, plot the logarithm of the diffuse radiance as a function of θ . The specification record gives JPHI and JPI as for ITYPE = 1. All depths are on the same plot.
- If ITYPE = 4, plot the logarithm of the total radiance as a function of θ , otherwise as for ITYPE = 3. All depths are on the same plot.
- If ITYPE = 5, make a polar plot of the diffuse radiances as a function of ϕ . The specification record gives ITHETA, the index defining a particular θ -cone:
 - If ITHETA > 0, upward radiances are plotted
 - If ITHETA < 0, downward radiances are plottedA separate plot is made for each depth.
- If ITYPE = 6, make a polar plot of the total radiances as a function of ϕ , otherwise as for ITYPE = 5.
- If ITYPE = 7, plot the logarithm of the diffuse radiances as a function of ϕ . The specification record gives ITHETA as for ITYPE = 5. All depths are on the same plot.
- If ITYPE = 8, plot the logarithm of the total radiances as a function of ϕ , otherwise as for ITYPE = 7.
- If ITYPE = 9, plot the logarithm of the total path function as a function of θ . The specification record gives JPHI and JPI as for ITYPE = 1. All depths are on the same plot.

Note: ITYPE = 5, 6, or 9 cannot be used in the listed code, since the required subroutines PPHIPLR and PPATH have not been written as of the date of compilation of this report.

§7A. PLOTTING RADIANCES

2. Code Listing

```
PROGRAM MPRAD(INPUT,OUTPUT,TAPE5=INPUT,TAPE6=OUTPUT,TAPE50,
1 TAPE98,TAPE99)
C
C ON NHM6/MPRAD
C
C THIS PROGRAM CONTROLS THE PLOTTING OF THE RADIANCES, USING THE
C FILE OF RADIANCE DATA WRITTEN BY PROGRAM 5 (TAPE50).
C
C ALL PLOTTING IS DONE USING STANDARD CALCOMP CALLS
C (TAPE98 AND TAPE99 ARE USED BY THE CALCOMP ROUTINES, AS
C IMPLEMENTED ON THE AUTHOR'S CDC CYBER 855 COMPUTER.)
C
C EACH PLOT IS GENERATED BY TWO TO FOUR FREE-FORMAT DATA RECORDS.
C
C THE FIRST RECORD GIVES ITYPE,NTIT,NYPLT WHERE
C ITYPE SPECIFIES THE TYPE OF PLOT TO BE MADE, AS DESCRIBED BELOW.
C NTIT.LE.0 IF NO TITLE FOR THE TOP OF THE PLOT IS DESIRED
C .GT.0 IF A TITLE FOR THE TOP OF THE PLOT IS TO BE READ IN
C NYPLT.LE.0 IF ALL Y LEVELS ARE TO BE PLOTTED
C .GT.0 IF NYPLT Y LEVELS ARE TO BE PLOTTED
C
C IF NTIT.GT.0, THE NEXT RECORD GIVES THE DESIRED TITLE
C
C IF NYPLT.GT.0, THE NEXT RECORD GIVES THE INDICES OF THE Y
C LEVELS FOR THE PLOTS
C
C THE LAST RECORD, THE SPECIFICATION RECORD, GIVES THE VALUES OF
C THE PARAMETERS NEEDED TO SPECIFY THE DETAILS OF THE PLOT
C
C IF ITYPE.EQ.1, MAKE POLAR PLOTS OF THE LOGARITHM OF THE DIFFUSE
C RADIANCE AS A FUNCTION OF THETA. THE SPECIFICATION
C RECORD GIVES JPHI AND JPI, WHICH ARE THE
C PHI INDICES OF TWO HALF-PLANES. NORMALLY PHI(JPI) =
C PHI(JPHI) + PI, SO THAT A PLANAR CROSS SECTION OF THE
C RADIANCE IS PLOTTED.
C A SEPARATE PLOT IS MADE FOR EACH DEPTH.
C
C IF ITYPE.EQ.2, MAKE POLAR PLOTS OF THE LOGARITHM OF THE TOTAL
C RADIANCE AS A FUNCTION OF THETA, OTHERWISE AS FOR
C ITYPE = 1.
C
C IF ITYPE.EQ.3, PLOT THE LOGARITHM OF THE DIFFUSE RADIANCE AS A FUNCTION OF
C THETA. THE SPECIFICATION RECORD GIVES JPHI AND JPI
C AS FOR ITYPE = 1.
C ALL DEPTHS ARE ON THE SAME PLOT.
C
C IF ITYPE.EQ.4, PLOT THE LOGARITHM OF THE TOTAL RADIANCE AS A FUNCTION OF
C THETA, OTHERWISE AS FOR ITYPE = 3.
C ALL DEPTHS ARE ON THE SAME PLOT.
C
C IF ITYPE.EQ.5, MAKE A POLAR PLOT OF THE DIFFUSE RADIANCES AS A
C FUNCTION OF PHI. THE SPECIFICATION RECORD GIVES
C ITHETA, THE INDEX DEFINING A PARTICULAR THETA CONE:
C IF ITHETA.GT.0, UPWARD RADIANCES ARE PLOTTED
C IF ITHETA.LT.0, DOWNWARD RADIANCES ARE PLOTTED
C A SEPARATE PLOT IS MADE FOR EACH DEPTH.
C
C IF ITYPE.EQ.6, MAKE A POLAR PLOT OF THE TOTAL RADIANCES AS A
C FUNCTION OF PHI, OTHERWISE AS FOR ITYPE = 5.
C
C IF ITYPE.EQ.7, PLOT THE LOGARITHM OF THE DIFFUSE RADIANCES AS A
C FUNCTION OF PHI. THE SPEC REC GIVES ITHETA AS
C FOR ITYPE = 5.
C ALL DEPTHS ARE ON THE SAME PLOT.
C
C IF ITYPE.EQ.8, PLOT THE LOGARITHM OF THE TOTAL RADIANCES AS A
```

§7A. PLOTTING RADIANCES

```

C           FUNCTION OF PHI, OTHERWISE AS FOR ITYPE = 7.
C
C           IF ITYPE.EQ.9, PLOT THE LOGARITHM OF THE TOTAL PATH FUNCTION AS A
C           FUNCTION OF THETA. THE SPEC REC GIVES JPHI AND
C           JPI AS FOR ITYPE = 1.
C           ALL DEPTHS ARE ON THE SAME PLOT.
C
C++++ WARNING: ITYPE = 5, 6 OR 9 CANNOT BE USED, SINCE THE REQUIRED
C           SUBROUTINES PPHIPLR AND PPATH HAVE NOT YET BEEN WRITTEN (CM, 3 JUNE 88).

B. Plotting Chromaticity Diagrams

The Natural Hydrosol Model computes *monochromatic* radiances. However, independent runs of the NHM can be made at various wavelengths, using wavelength-dependent input radiances and inherent optical properties, and the results can be combined to generate wavelength-dependent output.

It is often of interest, e.g. in remote sensing, to plot the ocean color on a standard C.I.E. chromaticity diagram. Program MPCHRO reads 13 data values corresponding to 13 wavelengths (400 nm, 425 nm, ..., 675 nm, and 700 nm). Each datum is obtained from a run of Programs 4 and 5, 13 runs in all. The data are processed using standard tristimulus functions, as described in Appendix C, and plots of the resultant color point are made on a 1931 C.I.E. chromaticity diagram.

In order to compute a correct color (e.g. for the upward radiance), the incident radiance on the water surface must have the correct color, i.e. wavelength dependence (corresponding, say, to the solar spectrum). The proper wavelength dependence of the incident lighting can be achieved by adjusting the value of SHTOTL (input record 6 in Program 4) in each of the 13 NHM wavelength runs. However, it is generally more convenient to make all NHM runs with SHTOTL equal to some nominal value, say $1.0 \text{ W m}^{-2} \text{ nm}^{-1}$. In this case, the output values of the 13 NHM runs must be adjusted before computing the chromaticity. Subroutine ATMOS uses a simple model atmosphere and solar spectrum (described in Appendix D) to weight the 13 data values according to wavelength and solar zenith angle before proceeding with the chromaticity calculations.

1. Input

Two records are read to specify the details of the plot, and then repeated pairs of records are read to specify the wavelength data to be plotted.

Record 1: LABPNT, IPLBLU, IATMOS

LABPNT	= 0	if the plotted points are not labeled.
	= 1	if each plotted point is numbered on the chromaticity diagram, and a separate table of numbers is plotted, along with a label for each number to identify the plotted points.
IPLBLU	= 0	if only the full chromaticity diagram is to be drawn.
	= 1	if only the "blue corner" of the chromaticity diagram is to be drawn. This is often useful for plotting ocean color, which usually lies in the blue region.
	= 2	if both the full diagram and the blue corner are to be drawn.
IATMOS	= 0	if the raw data values, $P(\text{LAMBDA})$, are to be used in computing the color.
	= 1	if the raw data values, $P(\text{LAMBDA})$, are to be transformed by the atmospheric model of Appendix D before use.

§7B. PLOTTING CHROMATICITIES

Record 2: ITOP

This record gives a title for the top of the plot. Up to 80 alphanumeric characters are allowed.

Record 3: ITITLE

This record gives a label for the plotted point. Up to 80 characters are allowed.

Record 4: THETPS, P(1), P(2), ..., P(13)

THETPS is the zenith angle, in degrees, of the sun in the run of Program 4 which generated the data. If IATMOS = 1, this value is used in the atmospheric model of Appendix D to correct the raw data values $P(I)$, $I = 1, \dots, 13$.

P(1) are the 13 data values to be used in computing the color. P(1) corresponds to wavelength 400 nm, P(2) to 425 nm, ..., P(13) to 700 nm.
:
P(13) Typically, P(I) is the radiance in a given direction at a given depth, or an irradiance at a given depth.

Records 5 and 6, 7 and 8, ...

Pairs of records of the same form as 3 and 4 are repeated for each point to be plotted. Up to 50 points are allowed by the dimensions in the listed code (see parameter MXPTS in program MPCHRO).

C. Plotting Data as a Function of Wavelength

If data have been generated for each of the 13 wavelengths described in paragraph B above, it is often desirable to plot the data as a function of wavelength. Program MPWAVE generates such plots.

1. Input

Three or four records are read to specify the details of the plot, and the pairs of records containing the wavelength-dependent data are read.

Record 1: ITITLE

This is a title for the top of the plot. Up to 80 alphanumeric characters are allowed.

Record 2: LABYAX

This is a label for the y-axis (the ordinate) of the plot. Up to 80 characters are allowed.

Record 3: NTRACE, ILOG, IAUTOY, IPLABL, IATMOS

- | | |
|--------|--|
| NTRACE | gives the number of data curves (traces) to be drawn on a given set of axes (i.e. on the same plot). (Up to 20 traces are allowed in the listed code; see parameter MXTRAC in program MPWAVE.) |
| ILOG | = 0 if the actual data values are to be plotted
= 1 if the logarithm (base 10) of the data is to be plotted |
| IAUTOY | = 0 if Record 3a specifies the y-axis scaling
= 1 if the plot program examines the data to determine convenient y-axis scaling |
| IPLABL | = 0 if the plotted curves are not numbered or labeled
= 1 if the plotted curves are to be numbered and labeled |
| IATMOS | = 0 if the raw data values, P(I), are to be used
= 1 if the raw data values are to be transformed by the atmospheric model |

Record 3a: YINCH, YMAX, YMIN, IDIV, NCODE

This record is read only if IYAUTO = 0. If IYAUTO = 1, the default values shown below are used.

- | | |
|-------|---|
| YINCH | (default value: 6.0). The length y of the y-axis in inches. The x-axis is always 6.0 inches long and is labeled with wavelength values. |
| YMAX | (default: internally generated). The maximum y value, used to label the y-axis and scale the data |

§7C. PLOTTING WAVELENGTH DATA

- YMIN (default: internally generated). The minimum y value, used to label the y-axis and scale the data
- IDIV (default: 5 to 10, internally generated). The number of divisions in the y-axis labeling.
- NCODE (default: 8, see record 3b). The number of characters to be transferred in the FORTRAN ENCODE statement. See record 3b.

Record 3b: YFMT

This record is read only if IYAUTO = 0.

YFMT is an execution-time format used to generate data values for labeling the tic marks on the y-axis. It should end with ",2HΔ-)", which draws tic marks with the "-" in the 2HΔ-. The "Δ" symbol indicates a blank. The default is

(F6.2, 2HΔ-)

This generates tic mark labels of the form

123.45 }
←y-axis vertical line

where the "-" from the "2HΔ-" in the format is the plotted tic mark. The default value of NCODE = 8 is the total of 6 (from the F6.2) plus 2 (from the 2HΔ-).

The format

(F3.0, 2HΔ-)

would generate tic mark labels of the form

12. }

Now, NCODE = 5

Record 4: LABTRC

This is a label for the plotted trace. Up to 80 alphanumeric characters are allowed.

Record 5: THETPS, P(1), P(2), ..., P(13)

This record has the same form as record 4 of Program MPCHRO: THETPS is the solar zenith angle and P(I), I = 1, ..., 13 is the data value for wavelength I.

Records 6 and 7, 8 and 9, ...

Pairs of records of the same form as 4 and 5 are repeated for each trace to be plotted. Up to 20 traces are allowed on the same plot.

APPENDICES

$$\begin{aligned}
 h(\text{sky}) &= \sum_{u=1}^{m-1} \sum_{v=1}^{2n} N(u,v) \Omega_{uv} + N(m,\cdot) \Omega_m \\
 &= \sum_{u=1}^{m-1} \sum_{v=1}^{2n} N_0 (1 + C\mu_u) \Delta\mu_u \left(\frac{2\pi}{2n} \right) + N_0 (1 + C\mu_m) 2\pi\Delta\mu_m \\
 &= 2\pi N_0 \sum_{u=1}^m (1 + C\mu_u) \Delta\mu_u \\
 &= 2\pi N_0 \left[\underbrace{\sum_{u=1}^m \Delta\mu_u}_1 + C \underbrace{\sum_{u=1}^m \mu_u \Delta\mu_u}_{\frac{1}{2}} \right] \\
 &= 2\pi N_0 \left(1 + \frac{C}{2} \right) \tag{B.3}
 \end{aligned}$$

For a uniform sky, $C = 0$, and we get $h(\text{sky}) = 2\pi N_0$, as expected.

The plane irradiance $H(\text{sky})$ is given by 75/8.7, which reduces to

$$H(\text{sky}) = 2\pi N_0 \left(\frac{1}{2} + \frac{C}{3} \right) \tag{B.4}$$

after using $\sum_{u=1}^m \mu_u^2 \Delta\mu_u = \frac{1}{3}$. For a uniform sky, $C = 0$, we get $H(\text{sky}) = \pi N_0$, as expected.

The well-known cardioidal radiance distribution, which approximates a heavy overcast with no discernible sun, corresponds to $C = 2$.

Subroutine QASKY uses (B.2) as background for a point sun. Using this model, we can study the effects of going from all direct beam (the sun in a black sky) to all diffuse light (heavy overcast), while keeping the total scalar irradiance constant.

Let $h(\text{sun}) + h(\text{sky}) \equiv h(\text{total})$, and define the ratio of sky scalar irradiance to total scalar irradiance as

$$R \equiv \frac{h(\text{sky})}{h(\text{sun}) + h(\text{sky})} = \frac{h(\text{sky})}{h(\text{total})} \tag{B.5}$$

Using (B.3) and (B.5) and solving for N_0 gives

APPENDICES

$$N_0 = \frac{R \cdot h(\text{total})}{2\pi \left(1 + \frac{C}{2}\right)} \quad (\text{B.6})$$

and $h(\text{sun}) = h(\text{total}) \cdot (1-R)$.

Subroutine QASKY computes the quad-averaged input radiances by

$$N(u,v) = \frac{R(1 + C\mu_u)}{2\pi \left(1 + \frac{C}{2}\right)} h(\text{total}) \quad (\text{B.7})$$

for "sky only" quads, and

$$N(u,v) = \left[\frac{R(1 + C\mu_u)}{2\pi \left(1 + \frac{C}{2}\right)} + \frac{1-R}{\Omega_{uv}} \right] h(\text{total}) \quad (\text{B.8})$$

for the "sky + sun" quad. Note that for $R = 1$ (no sun) and $C = 0$ (uniform sky), each quad gets a quad-averaged radiance of magnitude $N(u,v) = h(\text{total})/2\pi$.

APPENDIX C. Computation of Chromaticity Coordinates

The standard way of displaying water color is the *chromaticity diagram**. The chromaticity coordinates X, Y, Z are given by

$$X = 680 \int_{400}^{700} P(\lambda) \bar{x}(\lambda) d\lambda \quad (\text{C.1})$$

with corresponding equations for Y and Z. Here λ is wavelength in nanometers, $P(\lambda)$ is a radiance or irradiance, and $\bar{x}(\lambda)$ is the tristimulus (color matching) function for red.

This integral can be approximated by Simpson's rule if the 400-700 nm interval is divided into an even number of subintervals. For runs with the NHM we choose 12 subintervals of width $\Delta\lambda = 25$ nm, and run the monochromatic NHM at the 13 wavelengths of $\lambda_1 = 400$ nm, $\lambda_2 = 425$ nm, ..., $\lambda_{13} = 700$ nm. Then X is computed by

$$X = 680 \frac{\Delta\lambda}{3} [P(400) \bar{x}(400) + 4P(425) \bar{x}(425) + 2P(450) \bar{x}(450) + \dots + 2P(650) \bar{x}(650) + 4P(675) \bar{x}(675) + P(700) \bar{x}(700)] \quad (\text{C.2})$$

* See, for example, *Hydrologic Optics, Vol. 1, Introduction*, by R.W. Preisendorfer, Pacific Marine Environmental Laboratory/NOAA, Honolulu, HI, pages 142-151. Available from NTIS as document no. PB-259793/8ST.

APPENDICES

The normalized chromaticity coordinates are given by

$$x \equiv \frac{X}{X+Y+Z}, \quad y \equiv \frac{Y}{X+Y+Z}, \quad z \equiv \frac{Z}{X+Y+Z}. \quad (\text{C.3})$$

The (x,y) normalized coordinates can be used to plot a point on a 1931 C.I.E. chromaticity diagram.

The table below gives the values of $\bar{x}(\lambda)$, $\bar{y}(\lambda)$, $\bar{z}(\lambda)$ for the 13 λ -values used in the NHM.

Tristimulus (color matching) functions \bar{x} , \bar{y} and \bar{z} *

λ	$\bar{x}(\lambda)$	$\bar{y}(\lambda)$	$\bar{z}(\lambda)$	weight for Simpson's rule integrations
400	.0143	.0004	.0679	1
425	.2148	.0073	1.0391	4
450	.3362	.0380	1.7721	2
475	.1421	.1126	1.0419	4
500	.0049	.3230	.2720	2

550	.4334	.9950	.0087	2
575	.8425	.9154	.0018	4
600	1.0622	.6310	.0008	2
625	.7514	.3210	.0001	4
650	.2835	.1070	0	2
675	.0636	.0232	0	4
700	.0114	.0041	0	1
sums	4.2699	4.2712	4.2617	
Integrals for $P(\lambda) = 1$	72319.	73005.	72170.	

Note that the integrals $680 \int_{400}^{700} \bar{x}(\lambda) d\lambda = 72319$, etc., agree to within 1%, which is the same order of accuracy as the output of the NHM.

Converting (x,y) into (dominant wavelength, purity)

Subroutine CHRMXY draws the spectrum locus of the chromaticity diagram by connecting 37 tabulated pure-color coordinates $[x_p(I), y_p(I)]$, $I = 1, \dots, 37$ to make a closed curve. The

* Taken from *Color Science* (2nd edition) by G. Wyszecki and W. Stiles, John Wiley & Sons, New York, 1982, Table II (3.31), pages 736-7.

APPENDICES

computed (x,y) point is then plotted on this diagram. For the plotted point (x,y) we can compute a dominant wavelength (or dominant color), λ , and a purity, p. For a point (x,y) on the diagram drawn by CHRMXY this is a simple exercise in analytic geometry, and proceeds as follows.

- 1) First compute the slope of the line between the white point (x_w, y_w) and each of the 37 plotted spectrum locus points $[x_p(I), y_p(I)]$, $I = 1, \dots, 37$.
- 2) Then compute the slope of the line between the white point (x_w, y_w) and the plotted point (x, y) .
- 3) Then search through the set of "spectrum locus slopes" from 1) until the slope from 2) is located between the I^{th} and $(I+1)^{\text{st}}$ spectrum locus slopes. We now know that the dominant wavelength λ will be somewhere between λ_I and λ_{I+1} , where λ_I is the wavelength of the I^{th} plotted spectrum locus point.

Since different pairs of points (x_1, y_1) , (x_w, y_w) and (x_2, y_2) , (x_w, y_w) can have the same slope, it is necessary to note if $x \leq x_w$ or $x > x_w$ and if $y \leq y_w$ or $y > y_w$. The slopes in the corresponding quadrant of the chromaticity diagram (lower left, etc.) can then be searched.

- 4) Compute the intersection point (x_i, y_i) between the line connecting the I^{th} and $(I+1)^{\text{st}}$ spectrum locus points and the line determined by the white point and the plotted point. The point (x_i, y_i) is computed from the solution of

$$\begin{cases} \frac{x_i - x_w}{y_i - y_w} = \frac{x - x_w}{y - y_w} \equiv s_1 & \text{the line determined by } (x, y) \text{ and } (x_w, y_w) \\ \frac{x_i - x_p(I-1)}{y_i - y_p(I-1)} = \frac{x_p(I) - x_p(I-1)}{y_p(I) - y_p(I-1)} \equiv s_2 & \text{the line determined by} \\ & [x_p(I), y_p(I)] \text{ and } [x_p(I+1), y_p(I+1)] \end{cases}$$

which gives

$$x_i = \frac{s_2 x_w - s_1 x_p(I-1) - s_1 s_2 [y_w - y_p(I-1)]}{s_2 - s_1} \tag{C.4}$$

$$y_i = \frac{x_w - x_p(I-1) - s_1 y_w + s_2 y_p(I-1)}{s_2 - s_1}$$

- 5) Given the intersection point (x_i, y_i) , compute the distance d_1 from $[x_p(I), y_p(I)]$ to (x_i, y_i) and the distance d_2 from (x_i, y_i) to $[x_p(I+1), y_p(I+1)]$. Then the dominant wavelength is

$$\lambda = \left(1 - \frac{d_1}{d_2}\right) \lambda_I + \left(\frac{d_1}{d_2}\right) \lambda_{I+1} \tag{C.5}$$

- 6) Compute the distance d_3 from (x, y) to (x_w, y_w) and the distance d_4 from (x_i, y_i) to (x_w, y_w) . Then the purity is

$$p = \frac{d_3}{d_4} \tag{C.6}$$

APPENDIX D. A Simple Model Atmosphere and Solar Spectrum

The input required by the NHM is the incident radiance *at sea level*. If the NHM is being used at only one wavelength, then the input spectral scalar irradiance can be set to some convenient value, say $1.0 \text{ W m}^{-2} \text{ nm}^{-1}$. However, if runs are being made at various wavelengths and the results are being combined, e.g. to compute colors, then the radiance on the water surface should account for atmospheric effects and for the wavelength dependence of the solar spectrum. It is usually most convenient to make all NHM runs with the same input, and then to correct the output when computing colors, etc. This is allowed by the linearity of the radiative transfer equation.

Subroutine ATMOS uses a crude model atmosphere which depends only on the solar zenith angle, θ_s , to incorporate atmospheric path length effects on the sun's direct beam. This routine also uses tabulated solar spectrum values to incorporate the wavelength dependence of the solar spectrum. The model is based on tabulated values of the scalar irradiance at sea level* for atmospheric conditions of

pressure = 760 mm Hg

2.0 cm of precipitable water vapor per unit of optical air mass

300 dust particles per cm^3 in the air

0.28 cm of ozone per unit of optical air mass

The optical air mass is 1 when $\theta_s = 0^\circ$ (the sun is at the zenith); it is $2 = \sec 60^\circ$ when $\theta_s = 60^\circ$, and so on. The scalar irradiance at sea level, $h_{SL}(\lambda, \theta_s)$, is given by

$$h_{SL}(\lambda, \theta_s) = h_s(\lambda) e^{-\alpha_\lambda \sec \theta_s} \quad (\text{D.1})$$

where $h_s(\lambda)$ is the solar scalar irradiance at wavelength λ , outside the atmosphere, and α_λ includes all scattering and absorption effects of the model atmosphere. The table below gives the values of $h_s(\lambda)^\dagger$ and α_λ^\ddagger .

* Taken from the *Handbook of Geophysics and Space Environments*, ed. by S.L. Valley, Air Force Cambridge Research Lab, 1965, page 16-19.

† These values are taken from *Hydrologic Optics, Vol. 1*, page 23. The associated solar constant is 1396 W m^{-2} , which is somewhat too large.

‡ From the *Handbook of Geophysics and Space Environments*. The associated solar constant is 1322 W m^{-2} , which is somewhat too low. The α_λ are rescaled to be consistent with 1396 W m^{-2} .
