## ABSTRACT

The Navy Medical Administrative Unit (NMAU) for the Monterey Peninsula has a challenging mission which encompasses many administrative tasks. Medical readiness and occupational health requirements are tracked for all Navy and Marine Corps personnel in the region. In order to fulfill their mission satisfactorily, it was necessary for NMAU to get an automated database management system. The Flight Surgeon at the Naval Postgraduate School works very closely with NMAU. The Flight Surgeon's administrative responsibilities would also benefit from a database system. Based on the requirements for NMAU a database system was designed and implemented in their clinic. Based on the Flight Surgeon's requirements the data base system was further analyzed in order to assist future upgrades that would employ the flight surgeon's requirements. The primary objective, however, was to get a system on line for NMAU that would enable them to effectively and efficiently execute their mission. The Navy Medical Administrative Unit Database System (NMAUDS 1.0) was the result of the previously described endeavors; it was written in dBASE IV version 1.5

## I. INTRODUCTION

This thesis designed and implemented a database system for the Navy Medical Administrative Unit (NMAU) at The Presidio of Monterey. NMAU supports all military units on the Monterey Peninsula with Navy and Marine Corps personnel assigned. The list of units include The Naval Postgraduate School (NPGS), Fleet Numeric Oceanographic Center (FNOC), Naval Security Group Detachment (NSGD), Naval Telecommunications Center (NTCC), Marine Corps Detachment (MCD), Personnel Support Detachment (PSD), Navy Research Laboratory (NRL), Defense Manpower Detachment Center (DMDC), and Branch Dental Clinic (BDC). The implementation of a database system greatly reduced the work hours spent on specific administrative tasks that are instrumental in accomplishing NMAU's principal task of medical readiness. The primary function of the database system is to maintain the necessary occupational health information on Navy and Marine Corps personnel. From this database standard reports are generated and ad hoc queries and reports are created.

The database design also considered the Flight Surgeon's functional requirements. Located at NPGS, the Flight Surgeon works closely with NMAU, as over seventy-five percent of the personnel they maintain records for are assigned to NPGS. The Flight Surgeon also performs the medical review portion of

physical exams on all Navy and Marine Corps personnel. This was done so that in the future the Flight Surgeon could have access to the database, thus assisting that office's reporting and query needs. The Navy Medical Administrative Unit Database System version 1.0 (NMAUDS 1.0) is written in dBASE IV version 1.5. NMAUDS is implemented on a MS-DOS-based personnel computer with future intentions to implement the database onto a Local Area Network (LAN) with the dBASE IV LAN version.

#### **A. BACKGROUND**

NMAU previously had a database designed with dBASE III in 1990 by the Officer In Charge (OIC) at the time. The dBASE III database system, in partial working order when this thesis began in January 1993, broke down and became incapable of performing any functions in April, 1993. Due to three facts the previous system had little use in the creation of NMAUDS 1.0. First, some requirements have changed since it's creation and there were no considerations in the dBASE III database system for future requirements flexibility. Second, there was very little documentation and therefore the code was very difficult to analyze. Third, it appeared to have many bugs as it was unable to accomplish its originally designed tasks.

NMAU presently maintains medical records for approximately two thousand Naval and Marine Corps personnel. The personnel encompass all possible Naval and Marine Corps career

descriptions and therefore have varying occupational health requirements. The challenging task of maintaining accurate readiness information is exacerbated by the following issues.

The commands that are supported are scattered about the Monterey Peninsula and are often in no way affiliated with each other. Personnel rotate through in very large numbers. An average of approximately three hundred people arrive and depart in the same period of time four times a year during academic quarters at NPGS and DLI. NMAU is a detachment from the Directorate for Community and Occupational Health (DCOH) at the Naval Hospital Oakland (NHA). Consequently NMAU support resources are over one hundred miles away. Finally, they operate out of the Medical Health Clinic on the Presidio of Monterey which is an Army base without a Naval headquarters.

Another unique characteristic of NMAU is that the bulk of the medical services were done, when this thesis began, by a civilian unit Primary Medical Care for the Uniformed Services (PRIMUS) based at the health clinic on the Presidio of Monterey. There is additional support from Silas B. Hayes Army Community Hospital on Fort Ord in Marina. Physical exams are conducted by PRIMUS with the exception of the medical review which is done by the Flight Surgeon. This arrangement changed beginning 01 August 1993 when the Army replaced PRIMUS with a detachment of doctors and medics from Silas B. Hayes.

There is one officer and six enlisted personnel (corpsman) allotted to NMAU. They are currently understaffed by one corpsman. The unit's purpose is to ensure that personnel get their medical requirements completed and that their records are properly documented. With eighteen hundred records to track, minimal support, a decentralized organizational structure, and a dynamic environment, the management challenge is noteworthy. This database system will enable NMAU to quickly list personnel deficiencies and status reports thereby saving countless work hours for the unit.

#### **B. CHAPTER DESCRIPTIONS**

Chapter II is a system analysis. The operating environment is studied by means of surveys followed by a specific diagraming process. A description of survey and diagraming methodologies are also provided. The chapter is concluded with requirements specifications as they pertain to data, reports, and hardware and software issues.

Chapter III is a summary of the design process followed while developing NMAUDS. The chapter begins with a small discussion of database concepts and how they are related to this system. Entity relationship diagrams are defined and the models created for this project are addressed. The normalization process is reviewed with respect to this database system. The final section in this chapter provides

commentary of the data dictionary and its benefits to database system design.

Chapter IV discusses the final phases involved with establishing a database system. These phases are the development portion of the process and they include programming, testing, and system implementation. Database security theory and how it applies to NMAUDS is discussed in the section following implementation and database maintenance issues concludes the chapter.

Chapter V is a conclusion. This conclusion does a short summarization of the thesis and addresses future modifications to the system created. Also included are lessons learned with respect to requirements for database management systems and how they change.

Appendices A-E supplement the previously described text. The appendices are; Data Flow Diagrams, Entity Relationship Diagrams, Data Dictionary, System Programs, and NMAUDS 1.0 Users Manual respectively.

## **II. SYSTEM ANALYSIS**

### **A. USER SURVEY**

#### **1. Methodology**

Surveys with the users are essential. No system can be designed without first understanding the current process intended for improvement. Users are defined in a database system as "people who need information from the database to carry out their primary business responsibility." (Hansen, 1992, p. 27) This includes everyone at the Navy Medical Administrative Unit (NMAU) in varying degrees. The primary questions one asks in the survey process are: "What are the functions and responsibilities of the organization? ...and... "What are the outputs and inputs?" (Whitten, 1989, p. 117) After this information is obtained determination of whether the process can benefit from a database system follows. If process improvement is possible the scheme for remodeling ensues.

The process includes formal and informal surveys. Formal surveys include scheduled appointments with predetermined questions. Informal surveys consist of touring the environment and asking questions about what is seen and what is not understood. Informal surveys continue throughout the system development process. In the system analysis for

this thesis, formal surveys were conducted with senior and experienced personnel and informal surveys conducted included all personnel.

## **2. Application**

The primary concern of the personnel surveyed was the accuracy of the data. NMAU must be able to rely on the database to supply accurate reports to their supporting commands. Many individuals are unaware of their occupational health requirements in the Navy and Marine Corps. Those who are aware are often delinquent in maintaining these medical requirements. As a result, the notification of personnel for medical actions due determine how proper medical readiness is maintained. Ease of data input and error checking therefore become one of the most critical areas in designing the application.

Reporting requirements are basic. Reports about different medical deficiencies are supplied to the commands on a regular basis. There is, however, an additional necessity for flexibility in reporting. For instance, there exists a report that goes to various commands and curricular offices at NPGS which informs these units which personnel lack a current Physical Exam for the Personnel Fitness Test (PFT). The PFT, a semiannual requirement, contains no requirement for when execution of the PFT should occur. Hence, the report must be

flexible enough to assist individual commands or curricular offices with the PFT report in any given month as requested.

In addition to the many customized reports to various commands and curricular offices, reports must go to Directorate for Community and Occupational Health (DCOH) as well. These are known in Naval Medicine as "morbidity reports." A morbidity report and a productivity report have the same purpose. In other words, morbidity reports demonstrate what an occupational health unit accomplished over a period of time. For example, fulfilling monthly requirements to determine how many Yellow Fever Immunizations were given. Morbidity information is also comprised of ad hoc prospects.

Another administrative task that NMAU performs is tracking the number of people who arrive and depart each month. They are called "check-ins" and "check-outs" respectively. The previous database assisted this process and was invaluable to NMAU. Check-in and check-out statistics are necessary for Morbidity data as well.

During the interview process there was reference to the possibility of NMAU getting a Navy wide database system that might assist NMAU and perform some of their requirements. This system's title is Surface Automated Medical System (SAMS). The possibility of acquiring this asset was originally factored into future design considerations. However, later determination demonstrated SAMS use had fallen

short of NMAU's needs due to NMAU's unique situation previously discussed.

Security is a concern because of the fact that NMAU must share the health clinic spaces with PRIMUS and other medical units assigned to the health clinic. No data on the system is classified. There is, however, a degree of sensitivity with personal medical information. Equally as important is the desire to protect the data from malicious or unintentional corruption.

A final unusual factor taken into account involved the future of NMAU's responsibilities. As a result of down sizing and restructuring in the military, the fate of DLI, Silas B. Hayes and, in fact, any military unit is subject to change. There are many possible scenarios for these military units. The responsibilities of NMAU may increase or decrease. Presently, the most likely result is that NMAU's responsibilities will either increase or remain the same.

Most of the Flight Surgeon's requirements overlapped those at NMAU. In addition to those requirements, the Flight Surgeon had two other requirements in which a database would assist him. The first was more data requirements, including more immunizations, dental readiness information, rare billet designations called special programs, HIV testing and security clearance. The second revolved around the ad hoc nature of the job. The staff office at NPGS generated non-standard medical readiness information.

## **B. DATA FLOW DIAGRAMS**

### **1. Methodology**

Before designing a database it is necessary to accumulate the information from the surveys to study the data flows and gain an initial profile. From this research various diagrams are constructed in order to assist the design process. These are Data Flow Diagrams (DFDs).

Data Flow Diagrams are not flow charts. They do not explicitly show flow of data through a system. They only show flow of data, storage of data and the processes that respond to and change data. (Whitten, 1989, p. 14)

This is known as the logical schema of a system. The logical data flow eliminates unnecessary specifics such as who does a task and how a task gets done. The logical schema is only involved with data. This logical view of the system is derived from the physical data flow which was analyzed and determined as a result of the survey process (Appendix A).

There are three types of logical DFDs used (Appendix A includes a DFD symbols recognition key). The First is the Context Diagram. The Context Diagram portrays the system as one process and that one process' inputs and outputs. The Context Diagram also identifies the External Entities. External Entities are people, organizations or other systems which interact with the system being analyzed but fall outside the boundaries of the system identified in the Context Diagram. The second diagram is the Systems Diagram. This diagram identifies the subsystems and primary data stores.

They are depicted with their inputs and outputs as well. Finally there are Lower Level or n-Level Diagrams. Lower Level Diagrams represent the processes and data stores within a subsystem. This method of presenting more detail from one diagram to the next is called exploding. Each process can explore further into Lower Level Diagrams.

## **2. Application**

The Context Diagram (Appendix A) for this system exhibits the primary functions of NMAU. The inputs are personnel medical records and requests for services. Three external entities, personnel or patients, supported units, and NHO receive the outputs.

The Systems Diagram (Appendix A) explodes the medical and occupational health services into three process and four data stores. The processes are Schedule Medical Service, NMAU Appointment and Flight Surgeon Appointment. The Data stores are Medical Records, Physical Exams Log, Immunization Log, and Flight Surgeon's Log. In order to determine the validity of a new system the new system should be compared to an accurate current system. Accordingly, the dBASE III has been taken out of the system because it became dysfunctional during the design process. Without the previous database NMAU's ability to complete their mission is greatly reduced. However, the Systems Diagram with dBASE III is depicted in Appendix A.

The only process exploded further is the NMAU appointments process (Appendix A). This is done to present greater detail in the report generation processes. New processes in this diagram are File Record, Provide Medical Services, Records Review and Create NMAU Reports.

## **C. REQUIREMENTS SPECIFICATION**

### **1. Data**

Identifying the data to be accumulated in the database was straight forward. Interviews were the primary determinant of essential data. However, often there are conditions in which the designer may anticipate how the system can benefit the user when the user can not. Therefore, some data fields, although not directly requested through interview, become a part of the design if acknowledged by the user as a future consideration. Notwithstanding, system designers must be careful not to over do their design.

The Data Dictionary (appendix C) is comprised of all the data fields required. Chapter III examines data dictionary methodology. The fundamental categories of data are patient personal information, medical history, and command information. The Flight surgeon's desires increased the number of fields in each category.

## **2. Reports**

The reports can be broken into three classifications. They are Command Notification Reports, Internal Administrative Reports and DCOH Reports.

Command Notification Reports inform the supported units of individuals who are due or delinquent in fulfilling their medical and occupational health requirements. They include readiness reports and Personnel Lacking Current Physical Exams for the PFT or PFT reports. These reports have a few different variations depending on the period and parameters of the specific report.

Internal Administrative Reports are for house keeping within NMAU. They include check-in verification, check-out verification and a shelf list. Check-in verification includes verifying check-in data received from PSD. Check-out verification is necessary for preparation of personnel transfers but its primary use is a cross reference prior to removing data from the database or whatever mechanism is in use for tracking readiness. The shelf list displays the records in the sequence in which they are stored on the shelf. This is very useful for finding records or for the mandatory annual record review. The records are shelved by the last four digits of the social security number followed by the middle two digits succeeded by the first three digits. The Terminal Digit Filing System is the label given to this filing technique.

DCOH Reports deal primarily with morbidity. The necessary information is totaled on the database and transferred to an official report sent to NHO. The database may be authorized to generate this report in the future. This can be dealt with in a follow-on thesis by performing an upgrade of this application.

### **3. Hardware and Software**

Often in systems design a portion of the design process includes selecting the hardware that best satisfies the specifications while staying within a budget. Sometimes the designer must design with hardware decisions previously determined. The latter was the case at NMAU. NMAU had an IBM compatible Zenith 286 as the only available asset for a database. They were requesting new and more powerful IBM compatible 386 or 486 computers with LAN capabilities. The decision to request these computers had already been determined and the approval of the request was pending when this thesis began.

As a result, hardware specifications were previously determined with a worst case scenario of designing a database to run off the old Zenith 286. The best situation to hope for was an approval of The IBM compatible 486. The decision made by DCOH in July, 1993 furnished NMAU with an Infiniti 486 IBM compatible computer.

The software requirements were quickly narrowed down to two different Fourth Generation Languages (4GLs). They were dBASE IV and Paradox. This decision resulted from the fact that at the time the Navy had site licenses for both of those packages. Therefore, they both were within budgetary constraints.

After review, Paradox emerged as the better relational language. It was designed for Structured Query Language (SQL) a powerful query tool. On the other hand, dBASE IV's strengths were its ease of use. The decision to use dBASE IV was a result of that fact. Furthermore, dBASE IV does have relational capabilities.

NMAU's mission was driven more heavily by periodic scheduled reports. Their need for ad hoc inquiries was minimal and the reduced relational potential of dBASE IV surpassed the requirement for ease of use. NMAU's personnel turn over every two to three years. The individuals assigned to NMAU have diverse computer experience but the norm is the more relatively inexperienced individual. Ease of use and wise ergonomics with respect to data entry are the paramount concerns since both software packages are capable of fulfilling all other requirements.

The Flight Surgeon's requirements are, in fact, primarily ad hoc driven. The ability to connect the Flight Surgeon into this database goes beyond the scope of this thesis and is an available topic for possible follow on thesis

work. Nevertheless, with respect to design the Flight Surgeon's requirements are analyzed. Two reasons guided this decision. First, if NMAU's responsibilities increase it is possible that their requirements would overlap further upon those of the Flight Surgeons. Additionally, dBASE IV version 1.5 has SQL capability and this application could be converted for the Flight Surgeon's use if desired.

### III. DATABASE DESIGN

#### A. DATABASE CONCEPTS

A database is an integrated collection of data, stored with a minimum of redundancy and structured such that multiple applications can share the data. Ideally, the data is structured independent of the programs that use it. This allows the structure to be changed without having to change the existing programs that use the data. (Whitten, 1989, p. 65)

Or more simply, "A database ... is a collection of interrelated, shared, and controlled data." (Hansen, 1992, p. 33)

Databases can be centralized, one control processing unit (CPU) utilized in one geographic area, or distributed, many CPUs in a single geographic area or one or more CPUs employed in more than one geographic area. The term geographic in this context varies in definition. For the purposes of this thesis a geographic location will mean the same floor of the same building. In which case Navy Medical Administrative Unit database system (NMAUDS 1.0) will be implemented on a centralized system which will be modified, in fiscal year 1994, to a distributed system on a Local Area Network (LAN) and through thesis follow on may be distributed further geographically.

The components of a database system do not consist of hardware and software alone. Users, procedures, and data

stores are equally important components. These components combined become an input-process-output apparatus. Better said, the system takes in information, processes it and produces useful information or intelligence.

## **B. ENTITY-RELATIONSHIP DIAGRAM**

### **1. Methodology**

The entity relationship diagrams (ERDs) assist in the system analysis as well as design. This model's most useful attribute is that it exhibits the relationships between the objects that are in a system. Specifically those objects about which ERDs store data. ERDs are most useful when developing a relational database system in which there is routine query needs.

The ERDs provide a more detailed examination of the data stores in the Data Flow Diagrams (DFDs). A DFD presents data in its dynamic stages. The data stores in DFDs are the static pictures of data between their metamorphosis. The ERD presents a detailed analysis of the data stores thus depicting data at rest.

Entity relationship diagrams do not depict flow or processing. They should not be read like data flow diagrams or flow charts. Entity relationship diagrams depict data at rest, data being stored. They also do not imply how data is implemented, created, modified, used or deleted. (Whitten, 1989, pp. 229-230)

ERDs consist of three components entities, relationships and attributes. These components are

illustrated on the diagram as squares, diamonds and non-square rectangles respectively (Appendix B). The names given to Entities are nouns. Therefore, entities are persons, places or things. Things are more often referred to as objects but they also can be an occurrence known as an event. Some examples are patient, command, and medical record. An immunization is an example of an event.

Relationships have verb titles. Relationships associate entities with each other. These relationships fall into three categories: one-to-one, one-to-many and many-to-many. "Every patient has one medical record," is an example of a relationship between a patient and that patient's medical record. This is a one-to-one relationship in which "Has" is the name of the relationship.

Entities are the items which tend to have data stored about them. Descriptive elements that describe entities are attributes. Attributes are also known as data elements. Relationships can have attributes but on the ERDs of NMAU this does not occur. Fundamentally, the attribute-entity join is a relationship but the relationship is so elementary that it is more easily described as an attribute. "A medical record maintains yellow fever shot dates," is an example of an entity-attribute relationship. The relationship "maintains" and the entity "yellow fever shot date" possess no other pertinent data. As a result, it is better to combine the two

and designate "yellow fever shot date" as an attribute of medical record.

Each entity must have an attribute which uniquely identifies every entity instance. This attribute is commonly called the "key" attribute. The key attribute has an important function in the data dictionary tables discussed in section D. Some attributes may not have a value for each entity, these attribute instances are called null values.

## **2. Application**

The ERD assembled for NMAU (Appendix B) deals primarily with personnel information. Medical Provider, Command, and Command-Division (departments, curriculums, or divisions) are three entities in the model whose data elements are presented predominately for future requirements. The remaining entities Patient, Medical History, Shot Record, Special Programs, and Dental Records have attributes which are necessary for current requirements. All eight entities are displayed with their attributes in Appendix B. The key attribute for all of these entities is Social Security Number (SSN) thus creating a data redundancy with the SSN element. These five entities can be combined into one entity but that picture yields less information about the data.

SSN is the key to the medical personnel entity as well. This would not be combined with the other entities whose key is SSN because there would be many null values since

only ten of the two thousand personnel in the database work at NMAU. In the future the database system can adopt this entity and its attributes to assist training and qualifications requirements of corpsmen.

Command Name is the key to the command entity. Unit Identification Code (UIC) and Curriculum Name are combined together to uniquely identify the Command Division entity. This is known as a combination or composite key. The Command and Command-Division entities, if implemented into the database system, will assist the flight surgeon's requirements. Within these two entities are the names of commanding officers and department/division officers. This induces a data redundancy which creates a tradeoff decision between the reward from increased information and the negative ramifications associated with this data redundancy. If implemented in an update of NMAUDS 1.0 this tradeoff will be a consideration.

A final point of interest for updates to NMAUDS is the possible addition of an entity called Female Tests. This entity comprises of the attributes Papanicolaou (PAP) smear and Mammogram. These tests are only performed on women. Since women incorporate far less than 50% of the records, if implemented, there would result an excess of null values. A relationship between Medical History and Female Tests (Appendix B) exists and can be considered in system updates if NMAU expands their readiness requirements. SSN would become

a redundant data item again and the tradeoff between reduced null values and increased data redundancy must be examined further prior to implementation.

### **C. NORMALIZATION**

The normalization process ensures data is stored in a manner that minimizes data redundancy and data anomalies while maintaining data integrity. Data anomalies occur when deleted data precipitates an additional unintended data loss or when updated data does not consequently update related data. These anomalies are known as deletion anomalies and update anomalies respectively. Improved data integrity, or consistency of data, as well as reduced data redundancy facilitate the elimination of anomalies.

The normalization process consists of a series of rules which refine the data elements for database implementation. Each stage of the normalization process produces a data set in a form. As a result, First Normal Form (1NF) is the name of the first revision, Second Normal Form (2NF) the second, and the names of the remainder continue accordingly except for a couple of exceptions.

Normalization occurs concurrently with the creation of ERDs as the two procedures compliment each other. Analysis of entities and their attributes, as groups of data, is the method for viewing data. Every non-key attribute in an entity can be determined by the key. For instance, SSN determines

the value for last name, first name, sex and every other attribute in the patient entity. These correlations are called a functional dependencies or in other words the attribute last name is functionally dependent upon SSN. Functional dependency is an important concept to understand in normalization.

First Normal Form eliminates all data attributes which can have more than one occurrence for each entity. For example, in the entity Medical History the attribute Special Program might have two values for a single entity instance. That is, it is possible for personnel to be members of more than one special program. Therefore, in order to place Medical History into 1NF each individual program is formulated into an attribute.

Second Normal Form requires that the entity satisfy the criteria for 1NF and that no other data attribute in the entity be functionally dependent upon a portion of a composite key. Therefore, in the development of the Command-Division entity no attribute may be functionally dependent upon curriculum or UIC alone.

Third Normal Form (3NF) requires that the entity satisfy the criteria for 2NF and that no non-key attribute functionally determines another non-key attribute. Several data elements were eliminated as a result of this condition. Last physical exam in combination with flight and date of birth determine next physical exam. Consequently, next

physical exam was eliminated as an attribute. The previous example is one of a few cases which once corrected condenses the data entities into 3NF.

Boyce-Codd Normal Form (BCNF) is satisfied if every attribute that functionally determines any other attribute is a key. When satisfied this form accomplishes 2NF and 3NF as well. If data is already in 3NF the only condition remaining to examine is whether any portion of a combination key can be determined by a non-key. This will need further consideration if the Command-Division entity is adopted for use in an upgrade.

Fourth Normal Form (4NF) requires that entities satisfy the criteria for 3NF and that multivalued dependencies be eliminated. A multivalued dependency exists when there are more than two attributes in an entity, at least one attribute is multivalued, and the values of two attributes determine a third. The present version of NMAUDS does not have any multivalued dependencies.

Among others the remaining forms include Fifth Normal Form and Domain/Key Normal Form. These remaining forms consist of abstract concepts and would not divulge any additional weaknesses that would effect NMAUDS 1.0.

#### **D. DATA DICTIONARY**

Expansion, amalgamation with additional applications, and evolution are fundamental concerns in database system design.

In order to enable successful future modifications, the Data Dictionary was created. A data dictionary provides definitions of all the data items in the database. Definitions are organized in data dictionary tables. Data items include fields, records, and files. Files associated by file type are also assembled into tables along with a description.

In the past, organizations recognized that data was their most precious and uncontrolled resource. As databases and database systems proliferate data administration became a serious problem. (Whitten, 1989, p. 354) The creation of the data dictionary concept standardized data and data file definitions in an effort to correct data administration problems. The data dictionary now provides a reference to diminish data redundancy and assure data integrity.

A data dictionary is different from a project dictionary. Project dictionaries are directories of data elements, data flows, system requirements, system inputs and system outputs created during the design of a large database system. The project dictionary's function is to assist with the management of massive amounts of new definitions that can overwhelm designers if not organized. A project dictionary was not done for the NMAU system (NMAUDS 1.0) because of the relatively small size of the system. The effort and time invested in a project dictionary would not have yielded an equivalent payoff.

The data dictionary for NMAUDS is displayed in Appendix C. The Patient, Medical History, Shot Record, Special Programs, and Dental Record entities and relationships are organized into one data file for the active database system. The attributes which serve current requirements are maintained in this data file (Appendix C). Also included are some additional attributes anticipated for requirements in the near future. These attributes include Flu shot, Unit Identification Code (UIC), and Human Immunodeficiency Virus (HIV) test.

Possible future database file structures are depicted in the data dictionary as well. Currently, the requirement for ease of data entry has driven the decision to incorporate all of the data elements into one file. This is a result of the fact that dBASE IV data entry forms associate directly to a single database file. If the entities were grouped into two or more files than as many data entry forms would necessitate, thus reducing the efficiency of data entry.

#### **IV. DATABASE MANAGEMENT SYSTEM DEVELOPMENT**

##### **A. PROGRAMMING**

dBASE IV version 1.5 is a fourth generation language (4GL) and as a result, much of the programming is done by the application through standard formats. This proved very helpful with application, menu, indexing and query programs. However, some of the requirements for reports made it difficult to use the report forms in dBASE IV. Flexibility is often lost when using standard program forms. As a result, a good deal of time was spent learning the dBASE IV programming language, a third generation language (3GL), which is also available in dBASE IV.

All but two reports, "NPGS Personnel Without a Curriculum or Department Code on File at Medical" and "Records List in Shelf Order", are programmed in the dBASE IV 3GL. Programming concepts taught in ADA at the Naval Postgraduate School (NPGS) and in Fortran at the Naval Academy were the foundation of knowledge used. Additionally, Programming in dBASE IV, [Ref 3], aided the programming process. System programs can be found in Appendix D.

Most of the procedures creating reports query the operator for report parameters. While designing operator inquiries, safeguards were implemented to prevent errors. Almost every

query is in a verification loop, a multiple choice entry format, or a unsatisfactory data entry loop. Many are protected by more than one of the previously stated precautions.

## **B. TESTING**

Testing is "the process of exercising or evaluating a system ... to verify that it satisfies specified requirements or to identify differences between expected and actual results." (Mynatt, 1990, p. 275) The testing phase of development overlaps substantially with the programming phase.

There are two principles of testing that were important to the testing strategy of NMAUDS. First, the purpose of the test plan is to uncover errors, not to demonstrate that the program can work. Second, one must recognize that it is impossible to test for all errors as there are an infinite number of possible data entries. Ergo, a test plan attempts to investigate as much of the program as possible with as little data as is reasonable.

Testing NMAUDS was done in the small and in the large. Testing in the small implies testing individual modules without respect to how they interact with other modules. The smaller modules were short programs, procedures, and functions. Testing in the large concentrates on passing test results between modules. Testing in the large included testing on report programs and applications.

Black-box testing was done primarily in the small but was also performed in the large, while white-box testing was done solely in the large. White-box testing ensures every path within program logic is traveled. A Logic-Flow Diagram is constructed so that all passages through the program logic is illustrated. Figure 1 on the following page is an example of a Logic-Flow Diagram used in the test plan for the program Readins2 (Appendix D). Two passes through the program will cover all modules at least once (a-b-c-d-e-f-g-h-j-k and a-c-d-e-g-h-i-a-c-d-e-g-h-j-l).

Black-box tests are created using the technique of equivalence partitioning. To use equivalence partitioning, every input condition specified is divided into a number of equivalence classes. Each equivalence class consists of a class or set of data items all of which are similar to each other on some relevant dimension. To create test cases, test data are chosen that include at least one piece of data from each equivalence class. When these test cases are executed, it is assumed that, if the module performs correctly on the test item from a particular equivalence class, the module will perform correctly for any other item from the same equivalence class. (Mynatt, 1990, p. 292)

For example a black-box test on the module which establishes the day value of the readiness report, a-b-c in Figure 1, would create three equivalence classes. The range for the value is one to thirty-one inclusive. Therefore the equivalence classes are:

1. less than one
2. one through thirty-one
3. greater than thirty-one

### White Box Test Plan Example

(Figure 1)

The final aspect of testing for NMAUDS occurred in implementation. The database system in its operating environment often gets tested in ways not thought of in the test plan. Additionally, the case in which test return values equal anticipated values but the anticipated values are erroneous, can only be discovered external to the test plan. Although not preferred, implementation will imminently discover some errors, preferably before acceptance. Only minor problems were discovered during the implementation of NMAUDS.

### C. SYSTEM IMPLEMENTATION

NMAUDS was implemented in two stages. The first stage entailed of database file structure and data entry forms. This was accomplished in order to permit data entry to begin prior to the completion of NMAUDS. The NMAU mission was beginning to suffer greatly due to the total loss of their dBASE III system. NMAU estimated that they would need at least four weeks for data entry and verification. As a result, while the remainder of the system was still in development data entry for the database began. Implementation of the first portion of the system was done on the IBM compatible Zenith 286.

The second stage involved a more traditional system implementation. Final testing of the system was performed in these operations as was alluded to in the previous section.

The complete process included training NMAU personnel how to use the system, generating all reports for random cross checking of data produced with personnel medical records, and performing all maintenance and update functions of the database. The entire design was implemented six weeks after the initial implementation phase on an IBM compatible Infiniti 486.

There were minor corrections to be made in both phases of implementation. Neither stage manifested any serious problems hence, the implementation was deemed a success.

#### **D. SECURITY**

Computer and database system security is not limited to preventing access to unauthorized users. The following is a list of requirements for security of database systems created by Charles P. Pfleeger [Ref. 5:p. 304].

1. Physical database integrity
2. Logical database integrity
3. Element integrity
4. Auditability
5. User authentication
6. Access control
7. Availability

The contents of Pfleeger's list consists of those security concerns confronted in the design of NMAUDS. The database administrator is the person who monitors these security

issues. At NMAU the Officer in Charge (OIC) has the position of database administrator.

Natural disasters, power failures, intentional physical destruction, and unintentional physical damage such as dropping a disk pack are examples of physical database security concerns. Some of these events can not be prevented and as a result, easy back up procedures and back up reminders are installed in the application. The database administrator has been advised to make frequent backup copies of the database to a separate storage medium a standard operating procedure (SOP). The database administrator has also been encouraged to maintain backup copies of the system as well. Additional SOP suggestions to sustain physical security include: keeping food and beverages away from the computer, prohibition of smoking in the computer room, and keeping the computer behind a locked door when unattended.

Logical database integrity means the elimination of update and deletion anomalies. This is accomplished in part by dBASE IV design and buttressed further by the normalization process.

Protecting element integrity was performed in part by the desire to create an easy and isolated data entry environment. The dBASE IV data entry form further assists this concern through default values, multiple choice data entry, and restriction of undesirable characters within specified fields. Examples include default field entry of the current date for

the check-in field, multiple choice options for command, and restricting all characters other than numbers from the SSN.

Auditability, the ability to track file and record accesses, can be useful in recreating a sequence of events for determining security transgressions. This capability is not offered with dBASE IV. Presently, the cost of a system that would provide this capability would exceed the benefits gained by one. Thus, the accountability security measure consequently received no further attention.

The final three security interests are dealt with using the dBASE IV protect system. This protect system offers three levels of security log-in, file and field access, and data encryption. User authentication is satisfied with the protect system. The OIC has been briefed separately and Navy Medical Administrative Unit (NMAU) personnel have been instructed on proper password procedures. Included in, but not inclusive to the instruction were two particular points. First, users were told to avoid short length passwords and words that identify or associate users to their passwords when selecting a password. Second, they were also encouraged to avoid commonly used password storage methods which do not properly safeguard passwords.

Access control protection is offered through dBASE IV field and file access. Field access was not implemented because individuals with the lowest level of access privileges are the data entry personnel and they would need access to all

fields for data entry. File access levels fall into five levels as seen in the matrix in Figure 2 below.

| <u>Access Privilege Levels</u> |               |                 |                 |                 |                 |                 |
|--------------------------------|---------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| <u>Access Privileges</u>       |               | <b>Level #1</b> | <b>Level #2</b> | <b>Level #3</b> | <b>Level #4</b> | <b>Level #5</b> |
|                                | <b>Delete</b> | Yes             | No              | No              | No              | No              |
|                                | <b>Extend</b> | Yes             | Yes             | No              | No              | No              |
|                                | <b>Update</b> | Yes             | Yes             | Yes             | No              | No              |
|                                | <b>Read</b>   | Yes             | Yes             | Yes             | Yes             | No              |

Security Access Matrix

(Figure 2)

The privileges associated with each level are on the vertical axis of the matrix. Availability will be directly controlled through the security levels depicted. The loss of necessary availability is another security issue in this final security list item. However, this will not be a factor until further applications are added to the system or new systems need to access the database.

Data encryption was deemed unnecessary due to the fact that all data items were unclassified. However, due to the private nature of most of the data, all of the data is considered sensitive. With all data elements designated sensitive, security is strengthened but flexibility is lost.

If another database management system design aspires to get access to the NMAUDS database, the higher level of security on NMAUDS would make the task more difficult. Finally, the OIC and NMAU personnel were instructed on the negative repercussions that can result from using unnecessary computer disks such as games and personnel text items on the same computer disk that the database and database system reside on.

#### **E. MAINTENANCE**

Maintenance is divided into four classifications: problem resolution, system modification, system expansion, and system upgrade or re-write. The last category is a combination of the first three. Problem resolution, if the system is tested and implemented properly, will account for the least amount of the total maintenance effort. System modification and system expansion will involve most of the maintenance labor, with estimates ranging between 70 and 85 percent.

NMAUDS' rigid design makes data input easy and system operation less intimidating for cyperphobic individuals. The tradeoff is that changes to, or maintenance of, the system is less flexible. Several reports, programs, and data elements of possible future requirements are installed in NMAUDS to avoid these maintenance efforts. Nonetheless, maintenance of some sort is inevitable as "every user's environment changes over time. The only difference is the rate of change. As change occurs, so do user requirements, and with change in

user requirements comes maintenance of the existing system."

- . (Inmon, 1983, p. 33) Effective program documentation and a thorough data dictionary are instituted in NMAUDS to assist these future projects.

## V. CONCLUSIONS

Design, development and implementation of the Navy Medical Administrative Unit Database System (NMAUDS 1.0) is the result of this thesis. The NMAUDS system provides the Navy Medical Administrative Unit (NMAU) with information which assists their primary functions: maintaining occupational health data and ensuring that the commands they support sustain high levels of medical readiness. NMAUDS supports this mission by accomplishing medical record maintenance and medical and occupational health status reports in a efficient and effective manner.

During the period of time NMAU was without automated support their mission capability suffered. Once implemented, the system was immediately put to use. Future updates of the system are a possibility as medical requirements change or as the areas of responsibility change for NMAU.

Research of the Flight Surgeon's requirements was an additional focus of this thesis. A potential upgrade of this database system or a new database system sharing the NMAUDS database are plausible follow on projects as well. The data dictionary supplies valuable information to any future undertakings which expand or modify the system.

The tools provided in dBASE IV were useful and time saving. This fact should be true for any upgrades to NMAUDS

1.0. The manuals provided with dBASE IV were also quite useful especially in the development phase.

The commonly noted problem of changing requirements was a factor throughout the course of this thesis. Lessons learned while dealing with this certainty are worth noting. Requirements changing were due to four circumstances; the users' environment changes, the users recognize after demonstration of the technology new uses for the system, the users fails to disclose all of their own requirements to the designer, and the designer misinterprets the users' explanation of their requirements. Only the first item on this list can not be avoided. The latter three items on the list, although not completely avoidable, can be minimized with good communication with the users. In this thesis communication flow was sporadic and requirements changes resulted. In retrospect, periodically scheduled, possibly biweekly, progress meetings would have been advantageous.

```

#### FUNCTION Dupechk

```

PARAMETER lc_dupefield, lc_tag
* Field and index.
ln_select = SELECT()
* Identifies the work area.
USE DBF() ORDER (lc_tag) AGAIN IN (ln_select)

```

```

* Opens DBF and uses current DBF indexed mem-var assigned
* to lc_tag.
ll_dupe = SEEK(lc_dupefield, ln_select)
* ll_dupe assigned to duplicate field.
USE IN (ln_select)
* Closes DBF in the work area.
RETURN .NOT. ll_dupe
* Returns non_duplicate field value.

**APPENDIX E: USER'S MANUAL**  
**TO THE NAVY MEDICAL ADMINISTRATIVE UNIT**  
**DATABASE SYSTEM**

**I. INTRODUCTION**

The purpose of this manual is to provide a step by step explanation of the Navy Medical Administrative Unit Database System (NMAUDS 1.0). This manual is provided solely for the purpose of using NMAUDS 1.0. Any maintenance of the system will require the thesis document provided and/or knowledge of dBASE IV version 1.5. For further guidance in dBASE IV refer to the manuals issued with dBASE IV software.

**II. STARTING NMAUDS**

There are three recommended methods to initiate NMAUDS.

- (1) From a DOS batch file that will access the dBASE subdirectory, start dBASE IV, and execute MEDICAL.APP.
- (2) From a menu system which will execute the batch file previously described in option (1).
- (3) From the dbase dot prompt by typing [DO MEDICAL.APP].

NMAUDS.BAT is the batch file originally dispensed with NMAUDS 1.0.

Figure F-1 Welcome Screen

The first screen displayed in NMAUDS is the welcome screen Figure F-1. To continue beyond the welcome screen press <ENTER>.

### III. MENU OPERATION

The first menu in the system, the main menu, illustrated in Figure F-2 provides three options. The options can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. All three selections produce additional menus. Deselecting these menus is accomplished by pressing <ESC> or <Escape>.

Figure F-2 Main Menu

#### A. REPORTS MENU

Figure F-3 is an illustration of the reports menu. The options on this menu can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. The first three selections on this menu exhibit an additional menu and they are discussed in sub-sections 1-3 below. All reports query the operator for necessary report parameters. Report parameter inquiries are self explanatory.

The fourth option on this menu is **Morbidity Report**. When selected, by pressing <ENTER>, the morbidity program is executed. The program will retrieve from the user the month of the report.

| Reports                                                                                                                                                                             | Update Data | Exit |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------|
| Physicals Needed for PFT<br>Checkout Reports<br>Medical Readiness Reports<br>Morbidity Report<br>Filing Report (Shelf-list)<br>HIU Report<br>NPGS personnel lacking a code<br>----- |             |      |

Use the arrow keys to highlight, ENTER to select and ESCAPE to return.

Figure F-3 Reports Menu

The fifth option is **Filing Report** (Shelf-List). When selected, by pressing <ENTER>, the filing report program is executed. That is, all of the records are shown in the order by which they are filed, the terminal digit filing system.

The sixth option on this menu is **HIV Report**. When selected, by pressing <ENTER>, the HIV report program is executed. All personnel who have not had an HIV test within the last year are listed.

The seventh option on this menu is **NPGS personnel lacking a code**. When selected, by pressing <ENTER>, a report program is executed which displays the names of those individuals who do not have their HIV code in the database.

Figure F-4 Physical Exams for PFT Reports

#### 1. Physicals Needed for PFT

Physicals Needed for the PFT is the first item in the Reports Menu. When selected by pressing <ENTER> an additional menu is displayed. Figure F-4 is an illustration of this menu. The options on this menu can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. Deselecting this menu is accomplished by pressing <ESC> or <Escape>.

The first option on this menu is **Physical exam due today for PFT**. When selected, by pressing <ENTER>, a PFT report program is executed which displays pertinent information on individuals who do not have current physical exams for the PFT.

The second option on this menu is **PE due for PFT (Query for month)**. When selected, by pressing <ENTER>, a PFT report program is executed which displays pertinent information on individuals who will not have current physical exams for the PFT in the month chosen by the operator.

The third option on this menu is **PE due for PFT (Query for Curriculum)**. When selected, by pressing <ENTER>, a PFT report program is executed which displays pertinent information on individuals who will not have current physical exams for the PFT in the month chosen by the operator.

## 2. Checkout Reports

Checkout Reports is the second item in the Reports Menu. When selected, by pressing <ENTER>, an additional menu is displayed. Figure F-5 is an illustration of this menu. The options on this menu can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. Deselecting this menu is accomplished by pressing <ESC> or <Escape>.

The first option on this menu is **Marked Records Report**. When selected, by pressing <ENTER>, a report program is executed which displays the names of individuals whose records are marked for deletion.

The second option on this menu is **Checkouts as of today**. When selected, by pressing <ENTER>, a report program is executed which displays pertinent information on individuals who have check-out dates before the date of the report.

Figure F-5 Check-out Reports

The third option on this menu is **Checkouts as of the month given**. When selected, by pressing <ENTER>, a report program is executed which displays pertinent information on individuals whose check-out dates are prior to the date chosen by the operator.

### 3. Medical Readiness Reports

Medical Readiness Reports is the Third item in the Reports Menu. When selected by pressing <ENTER> an additional menu is displayed. Figure F-6 is an illustration of this menu. The options on this menu can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. Deselecting this menu is accomplished by pressing <ESC> or <Escape>.

| Reports                                                                                                                                                                         | Update Data                                                                                                                                      | Exit |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Physicals Needed for PFT<br>Checkout Reports<br><b>Medical Readiness Reports</b><br>Morbidity Report<br>Filing Report (Shelf-list)<br>HIU Report<br>MPGS personnel lacking a co | Medical Readiness for time period given<br>Medical Readiness as of today<br>Medical Readiness Unit Report<br>One Stop Check-out Readiness Report |      |

Use the arrow keys to highlight, ENTER to select and ESCAPE to return.

Figure F-6 Readiness reports

The first option on this menu is **Medical Readiness for time period given**. When selected, by pressing <ENTER>, a readiness report program is executed. This report displays all the readiness data for individuals who are delinquent in at least one readiness field for the time window provided by the operator.

The second option on this menu is **Medical Readiness as of today**. When selected, by pressing <ENTER>, a readiness report program is executed. This report displays all the readiness data for individuals who are delinquent in at least one readiness field as of the date of the report.

The third option on this menu is **Medical Readiness Unit Report**. When selected, by pressing <ENTER>, a readiness

report program is executed. This report displays all the readiness data for individuals who are delinquent in at least one readiness field prior to the date provided by the operator. This report option displays only the individuals from the curricular office (curric\_div) assigned by the operator.

The fourth option on this menu is **One Stop Check-out Readiness Report**. When selected, by pressing <ENTER>, a readiness report program is executed. This report displays all the readiness data for individuals who are delinquent in at least one readiness field and are marked for deletion. This report option displays only the individuals from the command assigned by the operator.

#### B. UPDATE DATA

Figure F-7 is an illustration of the Updates menu. The options on this menu are all related to the maintenance of the database. Each option in the menu activates a program which executes one or more functions which permits the operators to perform database maintenance tasks easily.

The last option on this menu, **Delete checkouts** is only useful if accurate checkout data is able to be maintained. **Mark records for deletion, Unmark records for deletion, and Delete marked records** when used in conjunction also assist in check-out database management. "Mark records for deletion" marks records for deletion identified by social security number (SSN). "Unmark records for deletion" un-marks errantly

Figure F-7 Update Data

marked records marked for deletion also identified by SSN. "Delete marked records" purges marked records from the database and packs the remaining records.

The sixth and seventh options on this menu expedite some of the back up procedures needed in database maintenance. **Backup DBF** creates a duplicate data file for NEW\_DATA.DBF called NEWDATBK.DBF. **Restore backup to active DBF** copies the former NEWDATBK.DBF back-up copy to the active database file NEW\_DATA.DBF. This is helpful if the active database file was inadvertently altered.

Figure F-8 is an illustration of the data input program that appears when **Add Records**, the first item on the Update Data menu, is selected. Data input is made easy through

multiple choice options and default values. If a duplicate SSN is entered the error message; "Editing condition not satisfied (Press SPACE)" will appear. The entry for individuals allergic to an immunization is "11/11/11" which is also the default value for these fields. Deselecting the data entry form is accomplished by pressing <ESC> or <Escape>.

The second option on the update data menu is **Single Record Retrieval**. When selected, by pressing <ENTER>, a program is executed which retrieves specific records, identified by SSN, for browse or edit. Returning to the Update Data menu is accomplished by pressing <ESC> or <Escape>.

| Records Organize Go To Exit |      |            |           |          |            |             |  |            |  |
|-----------------------------|------|------------|-----------|----------|------------|-------------|--|------------|--|
| SSN                         |      |            |           |          |            |             |  |            |  |
| LASTNAME                    |      |            | FIRSTNAME |          |            | INITIAL     |  |            |  |

| FOX                         | POL  | FFD        | WF        | TD       | TYF        | ESC         |  |            |  |
| LAST FE                     |      |            | HIU       |          |            | AUDIO       |  |            |  |
| FLIGHT                      | DIVE | HALO       | RAD       | ASBESTOS | RESPIRATOR | NONION RAD  |  |            |  |
| DATA ENTRY                  |      |            |           |          |            |             |  |            |  |

Figure F-8 Data Entry Form

The third option on the update data menu is **Edit Database**. When selected, by pressing <ENTER>, the database is retrieved in the browse or edit mode with the first record in the database in view. Returning to the Update Data menu is accomplished by pressing <ESC> or <Escape>.

### C. EXIT MENU

Figure F-9 is an illustration of the exit menu. The option on this menu can be highlighted with the arrow keys and selected by pressing <ENTER> while the desired option is highlighted. Selecting "Exit" will return the operator to the operating system. Returning to the main menu is accomplished by pressing <ESC> or <Escape>.

Figure F-9 Exit Menu

#### IV. BACK-UP DATABASE

The back-up procedures previously mentioned are useful but not inclusive. A back-up copy of the database should be updated daily to an external storage medium. This can be done by typing "copy C:\dbase\NEW\_DATA.DBF [drive containing storage disk]:" at the hard drive prompt (usually c:>).
