ABSTRACT

The injection molding process for elastomers was investigated for its applicability in the fabrication of end items for Army use.

A variety of elastomeric compounds was prepared and injection molded. Results indicate that most compounds which can be compression molded can also be injection molded. Rubber items having equivalent physical properties and dimensions were obtained from the two molding processes.

Injection molding reduces the time required for curing; eliminates the need to preform the rubber prior to molding; reduces the amount of mold handling; and lowers the rejection rate in comparison with compression molding.

TABLE OF CONTENTS

PROBLEM

To investigate the use and applicability of the injection molding process for elastomeric items used in Army equipment.

To determine whether properties of injection molded items are comparable to those of compression molded items and whether the same dimensional tolerances can be maintained in both processes.

BACKGROUND

The growing interest in the injection molding process for elastomers is due to its many advantages over compression molding, which include: less stock preparation, shorter cure cycles, less physical handling of molds, improved product uniformity, lower finishing and labor costs and lower rejection rates.[1,2]

In compression molding, a quantity of preformed stock is placed in a heated mold cavity, the mold is closed and pressure and heat applied which cause the compound to fill the cavity with any excess being forced out as flash.

In the injection molding process, the mold is closed and the rubber compound is then injected into the preheated mold with a source of pressure external to that applied to close the mold. The external pressure can be applied by a screw or ram. Ram type injection which can be continuously loaded and automatically controlled has been successfully used commercially for several years.

APPROACH

In order to determine the effect of mold temperature and cycle time on properties of injection molded items, a conventional type neoprene compound was cured at three different mold temperatures with cycle times ranging from 1/2 to 5 minutes.

Neoprene, nitrile and SBR compounds commonly used in the fabrication of Army end items, were compression and injection molded. Physical properties were determined in order to compare the two types of processing.

1. Z. J. Dorko, J. Timar, J. Walker, "Injection Molding, Compounding & Equipment," Rubber World, 148, 29-52, July 1963.
2. W. F. Watson and D. A. W. Izod, "Injection Molding of Rubber," Rubber World, Vol. 155, No. 5, February 1967.

A series of compounds was prepared to determine the effect on physical properties of several conventional curing systems when used with injection molding.

Compounds based on an SBR masterbatch were vulcanized with different cure systems in an attempt to reduce the injection molding cycle to one minute or less. Several polyurethane based compounds containing a coagent in a peroxide cure system were included in the study. The use of coagents with conventional peroxide curing systems has been found to have a beneficial effect on properties when used with certain base polymers.[3]

Injection molded compounds were developed to meet specific grade requirements of MIL-R-3065 and MIL-STD-417.

Bonding of rubber to metal was investigated to determine if special bonding procedures would be necessary when using the injection molding process.

Formulations for compounds used in this study are given in Table I. Compounds were mixed in an internal Banbury mixer with curatives added on a two roll mill.

Physical properties of compression molded rubber were obtained on standard 6 x 6 x 0.075 inch, ASTM tensile sheets cured in a 24 x 24 inch platen hydraulic press under 1000 psi. pressure.

Injection molding was accomplished with a 100 ton, vertical ram type machine with 14 x 14 inch platens, capable of delivering a 7-9 ounce shot. The cylinder and platens are steam and electrically heated respectively, while both ram and press are operated hydraulically. A front view is shown in Figure 1. The machine is capable of either manual or semi-automatic operation. Circular pads (0.1 inch thick x 5.5 inches in diameter) were molded for test. The pads were removed hot and air cooled. Molding and machine conditions are listed in the data tables.

All testing was carried out according to ASTM procedures.

RESULTS AND DISCUSSION

Initial work showed that stress-strain properties of injection molded SBR, nitrile and neoprene compounds, cured with conventional curatives, did not change appreciably with mold temperature over the range 380 to 420°F. nor with time from 1 minute to 5 minutes. Table II shows the effect of time and mold temperature on the properties of a neoprene compound (524-2).

Compounds of SBR, nitrile and neoprene were cured by both compression and injection molding. Table III presents a comparison of properties obtained on pads compression molded for 30 minutes at 307°F. and injection molded 2 minutes at 400°F.

Variations of injection cylinder temperature had a negligible effect on stress-strain properties but exhibited considerable influence on flow and end item appearance.

Table IV presents a comparison of properties obtained on compression and injection molded test pads of three different elastomers cured with conventional curing systems and of compression and injection molded silicone compounds with and without post cure. Results indicate that the over all properties of injection molded sulfur donor (methyl tuads) cured rubber are better than injection molded sulfur cured compounds. The ultra fast curing system of Tetrone A and Captax could not be controlled and premature curing took place in the nozzle.

Injection molding of peroxide cured compounds met with varying degrees of success. Silicone and EPDM compounds could be successfully injection molded at 400°F. An SBR compound required a reduction in cure temperature to 350°F. in order to obtain acceptable pieces. A compound based on NBR could not be injection molded at the reduced temperature of 350°F. due to premature curing in the sprue and runner system. The successfully injection molded peroxide cured samples exhibited improved compression set values compared with sulfur or sulfur donor cure systems.

Post curing of compression and injection molded silicone elastomers produced no improvement in stress-strain properties and only slight improvement in compression set values.

Table V presents the data obtained on SBR compounds prepared in an attempt to reduce the injection cure cycle to one minute or less. Stress-strain properties for 1/2 minute injection molded samples compare favorably with

those molded by compression for 30 minutes, however, an injection molding cycle of one to two minutes was required in order to obtain compression set values equivalent to those of compression molded samples. The compound which employed cadmium oxide in place of zinc oxide displayed the best over all properties for short cycles. At a cure temperature of 420°F., samples injection molded for 90 seconds had properties equal to those of compression molded samples, including compression set.

The incorporation of coagents, tri allyl cyanurate and di allyl adipate into peroxide cured Genthane S compounds resulted in improved properties, as shown in Table VI. The use of coagents in Genthane SR compounds resulted in slightly poorer properties. This is possibly due to incompatability between the coagent and the TDI dimer required to give Genthane SR improved oil and water resistance.

During the course of this investigation, several orders for production quantities of end items were received, which if filled by injection molding would result in a reduction in cost and time required to complete the orders.

Compounds were prepared and test pads injection molded to determine their conformance to grade requirements of Specification MIL-R-3065 and MIL-STD-417. Physical properties and grade requirements are presented in Table VII. Cure cycles of 2-3 minutes at 400°F. were usually sufficient to produce rubber meeting all the requirements of the specified grades. No difficulty was encountered in meeting the dimensional requirements with injection molded articles. The following dimensional tolerances were required for the filler gasket, item D of Figure 2.: Outside diameter - .004 inches, inside diameter +.003 inches and +.005 inches for thickness. These tolerances were unusually close for molded rubber items. Dimensions of injection molded articles can be controlled to a limited degree by changing injection pressure and/or injection cylinder temperature. Photographs of end items produced by injection molding are presented in Figures 2 and 3.

Some difficulty with air entrapment was experienced during the injection molding of end items, but changes in mold design eliminated this problem. The first molds made for injection molding of more intricate shapes than flat test pads, were made with close fitting sections in order to minimize flash. It was discovered that the close fit would not allow air to escape fast enough and some air became trapped by the incoming rubber. Modifications of the molds to provide more space between mating surfaces eliminate air entrapment but increased the amount of flash.

Several of the grade requirements specified that the rubber be bonded to metal (See Figure 3) during the vulcanization process. Rubber to metal bonding during injection molding presented conditions not normally encountered during compression molding. The force at which the rubber enters the mold plus the flow of rubber in filling the cavity had a tendency to wipe the bonding agent from the surface of the metal plates. The high mold temperature (400°F.) also contributed to the problem by producing a partial cure in the bonding agent before the mold filled.

A number of bonding agents were evaluated on steel plates using both a one and two coat system. Results are listed in Table VIII. A two coat system was required to provide adequate bond strengths. Diluting the components of the two coat system with suitable solvents produced some improvement. Adequate bond strengths were obtained using a primer coat diluted 1:1 with toluene and a cover coat undiluted. Using the above two coat system on anodized aluminum produced bonds which were stronger than the bonded rubber.

CONCLUSIONS

Most elastomeric compounds which can be successfully compression molded can be injection molded.

The sulfur donor cure system using methyl tuads produced the best over all properties for sulfur curable, injection molded compounds.

End items can be produced which have physical properties and dimensional tolerances equivalent to those of compression molded articles.

The successful injection molding of elastomeric items depends to a large extent on proper mold design.

The injection molding process in some cases is better suited for production items than compression molding. The mold for the cable closure assembly (Figure 2) was simpler to make for injection molding than for compression molding.

RECOMMENDATIONS

Injection molding of rubber items should be considered as a means of producing articles on a production basis. This method offers high quality articles at considerable reduction in rejected pieces, cost of operation and handling time.

13. ABSTRACT

The injection molding process for elastomers was investigated for its applicability in the fabrication of end items for Army use. A variety of elastomeric compounds was prepared and injection molded. Results indicate that most compounds which can be compression molded can also be injection molded. Rubber items having equivalent physical properties and dimensions were obtained from the two molding processes. Injection molding reduces the time required for curing; eliminates the need to preform the rubber prior to molding; reduces the amount of mold handling; and lowers the rejection rate in comparison with compression molding. INSTRUCTIONS

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization *(corporate author)* issuing the report.

2*a*. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2*b*. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7*a*. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7*b*. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8*a*. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8*b*, 8*c*, & 8*d*. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9*a*. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9*b*. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers *(either by the originator or by the sponsor)*, also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

(1) "Qualified requesters may obtain copies of this report from DDC."

(2) "Foreign announcement and dissemination of this report by DDC is not authorized."

(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
________________________."

(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
________________________."

(5) "All distribution of this report is controlled. Qualified DDC users shall request through
________________________."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring *(paying for)* the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as *(TS)*, *(S)*, *(C)*, *or (U)*.

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
