(Same)May '50Restr.U.S.English83
photos, diagr, graphs(Same)

A calibration was made to determine the sea-level and altitude characteristics of the P&W R-2800-32W engine. This engine is an aircooled, 18-cyl, double-row, radial power plant with a two-stage supercharger having a fixed-ratio main stage and a variable-ratio auxiliary stage. The dry weight of the engine is 2690 lb and the maximum specific outputs, based on 2300 bhp take-off rating, are 0.855 bhp/lb and 0.82 bhp/cu in. The specified fuel is Grade 115/145 AN-F-48 fuel. The calibration results, compiled in graphical form, indicate that the combinations of rpm and manifold pressures, as well as CAT and SFC, are well within the manufacturer's contract guarantees. Based on dynamemter results, combinations are also given additionally for high-altitude cruise operation.

OBJECT

1. The primary object of this test was to determine the sea-level and altitude characteristics of the Pratt and Whitney (P&W) R-2800-32W engine.

C

C

The second second

and the state of the

()

. 149

CONCLUSIONS

2. Calibration results indicate that the engine satisfactorily meets the manufacturer's contract guarantees and is capable of the following ratings:

		:	2			•	: Altitud	lo - Féet
;	* *	: Sur	• • • • • • • • • • • • • • • • • • • •	CAT :	ASRP			AEL
Rating	: RPM:							Dynamometer
Take-off	:2800:2	-		-	62.7	: .80	: Sea Level:	Sea Level
		<u>:Aux.</u>	LOW :			<u>.</u>		
Normal Rated	:2600:1	900: Part	ial:	88 :	51.5	.74	: Ŝea Level:	Sea Level
Sea Level	: :	:Aux.	Low :	:		:	:	
Military Rated	:2800:2			-		: : .80	: :Sea Level:	Sea Level
Sea Level	<u></u>	:Aux.	Low :		<u>^</u>	<u>:</u>	<u> </u>	
Normal Rated Critical Altitud					48.6	: .81	30,000	34,100
OITOICAL ALOIDUG	<u> </u>	•111 <u>211</u>	uear:	·		······································	•	
Military Rated			-	93 :	60.6	.90	30,000	32,200
Critical Altitud		:High	Gear:	:		• •	:	

* As guaranteed in reference (b)

These runs were made without the automatic manifold pressure regulator. Critical altitude performance would not be affected by the use of the Stromberg CO-3F Automatic Manifold Pressure Regulator, but sea-level manifold pressure requirements at normal and military rated powers would be somewhat increased because of a controlled throttle drop which is built into the regulator. Approximately 51.9 in. Hg ASRP would be required at normal rated, sea-level, and 63.1 in. Hg ASRP at take-off and military rated, sea-level, using the guaranteed SFC's.

3. Overpower runs at sea-level and high gear critical altitude, using Specification AN-F-48 grade 115/145 fuel, indicate that the engine is detonation limited at the following powers and operation is restricted to limited periods:

RPM	BHP	Super. Gear	<u>Altitude (Ft)</u>	Mixture Position	ASRP In. Hg.	CAT °F	<u>F/A</u>
2800	2540	Partial Aux. Low	Sea-Lëvel *	Ři ch	72.5	98	. 098
2800	2110	Min. Slip High Gear	26,600	Rich	72.2	9 <u>-</u> 5	•10

* These runs made with 4.0 in. Hg carburetor throttle drop as incorporated in the automatic Manifold Pressure Regulator.

and the second s

()

. -11)

(

4. The Stromberg PR-64B2 carburetor (No. 728821), metering according to the P.L. No. 390940-10 setting, produced satisfactory normal operation, starting, idling and acceleration characteristics. Mixture control runs, including instability checks, and detonation-limited mixture response runs indicated that the carburetor "normal" setting could be leaner throughout the range, with an attendent saving in fuel consumption. After approximately 100 hours of operating time, a variation in carburetor metering characteristics was noted, particularly in altitude compensation, and it was necessary to manually adjust the fuel flow for the remainder of the calibration to agree with the established limits.

5. Fuel conforming to the minimum requirements of Specification AN-F-48 (115/145) is satisfactory for use at the conditions shown in paragraphs 2 and 3. In addition, this fuel provides detonation-free operation at the powers shown in paragraph 2 at sea-level, with 100°F carburetor air temperature, and at the critical altitude with 125°F carburetor air temperature. Grade (100/130) fuel is not satisfactory for use with this engine except at reduced ratings (see Plates 37 and 38).

6. Operation of the Stromberg CO-3F Automatic Manifold Pressure Regulator (No. B-10077, P.L. No. 3909433) was satisfactory throughout the entire calibration.

7. Engine operation including starting, smoothness, and acceleration was satisfactory. The calibration was started using P&WA YR-2800-32W engine, No. P-28015, (a semi-production model) but a failure of the main accessory driveshaft after 24 hours of operating time (see Plate 54) necessitated its removal from the dynamometer stand. A production model P&WA R-2800-32W engine, No. P-28802, was installed in the dynamometer room and the entire calibration was conducted on this engine (253 hours of operating time). Following is a list of failures which occurred during the tests:

-4-

(a) No. 8 piston failure at 40 hours (see Plate 55), probably due to pre-ignition.

()

()

(1)

· +f.

- (b) À number of the cap screws holding the right distributor cover failed during the calibration. These screws sheared off and allowed the distributor cover to loosen. Failures occurred at 100,143 and 145 hours of operation.
- (c) At 147 hours of operating time, a broken distributor finger was found in the left distributor.
- (d) No. 8 piston and rings failed (scuffing) at 165 hours of operating time.

8. Operation of the BG RB19R spark plugs for most of the calibration was generally satisfactory; however, several instances of faulty plug operation were noted. The failure of No. 8 piston (see paragraph 7(a))which occurred after approximately 40 hours engine and spark plug time, indicated pre-ignition (see Plate 55), and it was found that the center electrode was missing from one of the spark plugs in this cylinder. A complete set of new spark plugs was installed, and after completing 60 hours of high power running (including approximately 6 hours of detonation-limited runs) the following failures were noted:

- (a) Three plugs with the ceramic core surrounding the center electrode broken, with pieces missing.
- (b) One plug with ceramic core broken and center electrode missing.
- (c) One plug with ceramic core cracked.

Spark plug operation was satisfactory for the remainder of the calibration.

9. Considerable trouble was experienced with auxiliary stage impeller stalling at high altitude cruise conditions even with an auxiliary stage "bleedoff" valve installed. Stalling was encountered at low rpm and manifold pressures during high altitude operation, and was first noted by a violent surge or pulsation in the airflow, followed by complete stalling of one of the dual impellers (right hand impeller usually stalled). This condition could be quite serious in an airplane installation since a violent power surge or loss of power occurs and the auxiliary stage inlet temperature of the stalled impeller increases rapidly (temperatures in excess of 240°F have been measured on the inlet screen). A further discussion of this subject may be found in paragraphs 38 and 39.

- 5 -

10. Using "normal" mixtures produced by the P.L. No. 390940-10 setting of the PR-64B2 carburetor, the cooling air baffle pressure drop necessary to maintain the maximum cylinder head and/or flange temperatures specified in reference (b) was as follows:

1

ŀ

4

()

Condition	ŔPM	: : BHP	Super : Gear :	Cooling Air Temp °F	Bafflé Pressure : Drop - In. H2O :
Take-off	2800	2300	Partial : Aux. Low :	•	8.4
Normal Rated Sea Level	2600	1900 1	: Partial : Aux. Low :	84	5.0
: Military Rated Sea Level	2800	: 2300	: Partial : Aux. Low ;	-	: 8,4 : : 8,4 :
: : Normal Rated : Critical Altitude	2600	: : 1500	: Min, Slip: : High Gear:		5.0
: : Military Rated : Critical Altitude :	2800	: 1800 :	Min. Slip: High Gear		9 . 2

11. The torquemeter functioned satisfactorily throughout the test. A constant of 158.3 checked dynamometer determined power within the specified ± 2 per cent.

RECONTENDATIONS

12. It is recommended that the Aeronautical Engine Laboratory determined altitude ratings shown in paragraph 2, rather than the values indicated in the Pratt and Whitney engine specification (reference (b)), be accepted as the actual operating characteristics of the engine.

13. The Stromberg PR-64B2 carburetor, metering in accordance with the "normal" and "rich" mixture positions of the P.L. No. 390940-10 setting, is recommended for use with this engine. It is also suggested that an investigation be conducted as to the possibility of leaning out the "normal" setting, particularly in the cruise range, and extending the cruise range to a higher airflow, in an effort to attain lower fuel consumption values over a broader range.

- 6 -

ABL-1122

3

14. Operation with fuel conforming to the minimum requirements of Specification AN-F-48 (115/145) using either P&V guaranteed or "normal" mixture (see Plate 39) fuel consumptions is recommended as satisfactory. Because of detonation limitations (see Plates 37 and 38), fuel of grade (100/130) is not recommended for use with this engine except at reduced ratings.

15. The Stronberg CO-3F Automatic Manifold Pressure Regulator, P.L. No. 3909433. is recommended as satisfactory with this type engine.

16. BG RB19R spark plugs are not recommended as satisfactory for use with this type engine. If it is found necessary to use these type plugs, inspections should be more frequent and the overheul time period should be decreased.

17. It is recommended that a complete investigation be made in regards to auxiliary stage impeller stalling, and corrective measures applicable. This program should be directed toward establishing values at which stalling is encountered in flight installations (FAU-5 airplane) and further evaluating the auxiliary stage "bleed-off" valve. It is believed that possibly an investigation of entrance ducting or vaneing would help prevent stall. The auxiliary stage "bleed-off" system is considered a wasteful process as it tends to increase high altitude cruise fuel consumption values and somewhat lowers the cruise speed critical altitudes. Based on dynamometer results, it is recommended that for high altitude cruise operation the following combinations of rpm and manifold pressures be used:

- (a) 2300 rpm, 36 in. Hg ASRP and above.
- (b) 2200 rpm, 37 in. Hg ASRP and above.
- (c) 2100 rpm, 38 in. Hg ASRP and above.
- (d) 2000 rpm, 39 in. Hg ASRP and above.
- (e) No high gear operation below 2000 rpm,

18. A torquemeter constant of 158.3 is recommended for Naval aircraft service use.

DESCRIPTION OF SUBJECT

19. The following is a brief surmary of the characteristics of the subject engine. Photographs of general views of the engine are shown on Plates 59 to 61. inclusive.

- (i) The important basic improvements and design changes made on this engine with reference to the R-2800-18W ("C"-model, two-stage, two-speed) engine previously calibrated (reference (c)) are as follows:
 - (1) Dual auxiliary stage impellers, driven at variable speed through hydraulic couplings.
 - (2) Stromberg CO-3F Automatic Manifold Pressure Regulator controlling both carburetor throttles and oil to auxiliary stage supercharger couplings.
 - (3) Stromberg PR-64B2 carburetor (updraft),
 - (4) No provisions for automatic spark advance.
 - (5) Accessory section completely redesigned. Starter drive now geared 3 to 1 compared to 1 to 1 for "C" models. Generator now located on top of rear case between dual auxiliary stage impellers.
 - (6) Longer connecting rods.
 - (7) Lighter cylinder heads with longer barrels.

- (8) Redesigned pistons with piston pin bosses higher, flat head, curved inside dome.
- (9) Provisions for double-acting propeller governor.
- (10) Strengthened propeller shaft.

A MANDEL OF THE DESIGN AND A SUPERIOR AND A SUPERIO

C:

()

- (11) Planetary gear arrangement (3 to 1) for accessory drive shaft.
- (12) Rear counterweight made lighter with more movement to cut down loads.
- (13) Use of higher main oil pressures (115 to 140 psi at normal rated speed).

METHOD OF TEST

Engines No. P-28015 and P-28802 were installed in No. 1W dynamometer 20. room for conduct of a sea-level and altitude calibration as requested by reference (a). The engine was attached to the dynamometer by means of a geartype coupling and extension shaft. A large rubber coupling was used to attach the extension shaft to the dynamometer and a flywheel was installed on the engine end of the shaft to improve the vibration characteristics. The first engine (P-28015) installed was a semi-production model, and was removed from the dynamometer room after 24 hours of operation when a failure of the main accessory drive shaft occurred (see Plate 54). A production model -32W engine was then installed and all calibration results shown in this report were obtained in this engine (253 hours of operating time). The auxiliary stage inlet and cylinder exhaust pressures (at the outlets of the F-47N airplane type exhaust collector) were maintained at the required altitudes unless otherwise noted. The oil and breathing systems were maintained at or near sea-level conditions, and the fuel system was vented to carburetor entrance pressure. A standard . complement of instruments as is normally used by this laboratory was employed to measure fuel, air, and oil flows, temperatures and pressures.

21. Fuel conforming to the requirements of Specification AN-F-48 (115/145) and oil of specification AN-O-8, Grade 1100 were used during these tests. The oil-in temperature and oil-out pressure were maintained at a pproximately 165°F and 15 psi gage, respectively.

22. F4U-5 airplane ducts, intercoolers and bleed-off valve (Part No. 128891) were installed (see Plates 53, 57, and 58) and suitable ducting was fabricated so that the intercooler outlets were connected to the plant exhaust system and the inlets were connected to the cooling air blower drum. A set of auxiliary intercoolers was placed in the cold air stream of the adjacent dynamometer room, and by suitable piping, water was cooled in these intercoolers and s prayed on the

- 11 -

face of the engine intercoolers. With this arrangement it was possible to attain the desired carburetor air temperatures except at very cold conditions, FAU-5 flight data were used to determine the intercooler effectiveness ratios which is used to calculate the required carburetor air temperatures. The following table shows the intercooler effectiveness ratios used during calibration:

£

()

* *	Altitude (Feet)		Military Speed : Eff. Ratio %			:
:	0 to 20,000		68	70	7 0	; :
;	20,000 to 30,000	:	64	68	7Ô	:
•	30,000 to 38,000	:	61	65	70	: : :

These ratios were calculated by the following formula:

Effectiveness Ratio = <u>Aux. Exit Temp. - Carb. Air Temp.</u> Aux. Exit Temp. - Std. Altitude Temp.

The carburetor air temperature used was the average of five thermocouples on the carburetor screen and one in the carburetor scoop.

23. A manual mixture control unit was attached to the carburetor (air pressure to the metering chambers) to obtain desired fuel flows for mixture control and detonation-limited runs,

24. Sperry detonation detecting units were adapted to the intake rocker boxes on each of the 18 cylinders. Detonation was limited to "incipient" conditions-defined as "one or more cylinders indicating detonation at irregular intervals, none indicating a definite frequency".

26. Plates 1 to 20 inclusive show the sea-level and altitude basic calibration curves. The altitudes, SFC's, manifold pressures, etc., plotted therein for the various speeds and powers are indicative of the values that are obtained in "rich" and "normal" mixture positions of the PR-64B2 carburetor incorporating the P.L. No. 390940-10 setting (see Plates 39 and 40). Temperatures at the auxiliary stage entrance ducts were maintained at standard altitude conditions, as were the exhaust pressures at the outlets of the F-47N airplane-type exhaust collector. Carburetor air temperatures (average of 5 thermocouples on the carburetor screen and one in carburetor scoop) were maintained (by use of the F4U-5 intercoolers) at the desired values depending upon F4U-5 intercooler effectiveness ratios (see Paragraph 22). The Stromberg CO-3F Automatic Manifold Pressure Regulator was set at sea level to obtain approximately military and normal powers at the critical altitude for 2800 and 2600 rpm respectively, the altitude then being raised in successive steps, without touching the regulator, until a full throttle power line was established. At 2400, 2200, and 2000 rpm, the regulator was similarly set to obtain 165 bmep at the critical altitude. At the lower speeds however, auxiliary stage supercharger stalling was encountered at critical altitudes, and it was decided to set the regulator to obtain 165 bmer at sea-level. The auxiliary stage "bleed-off" valve was installed and connected to operate as it does in the airplane installation. All data included in this report were obtained using a production Model R-2800-32W engine, No. P-28802, and using AN-F-48 (115/145) fuel unless otherwise noted. The following table shows the manifold pressures, airflows, fuel/air ratios, SFC's, carburetor air temperatures, using normal and rich mixture strengths, at normal, military, take-off and overpower conditions.

27. Plates 21 to 26, inclusive, show the cruise power altitude characteristic of the engine, at various power conditions and at 2200 and 1800 rpm. "Normal" mixture strengths were used throughout, and the same procedure of operation outlined in the preceding paragraph was employed. These runs were made to determine the operating conditions of maximum economy at these two cruise speeds. Data indicates that at 2200 rpm, with the present carburetor setting (P.L.No. 390940-10), maximum economy was obtained at approximately 33.5 in. Hg. manifold pressure. This coincides with the air flow at which carburetor enrichment begins at this speed. However, at approximately 26,000 feet it is necessary to operate at 37 in. Hg ASRP or higher to prevent auxiliary stage stalling. At 1800 rpm stalling was encountered at approximately 18,000 feet, regardless of the manifold pressure employed. Best overall economy was obtained at approximately 34 in. Hg ASRP at this speed. See reference (h) for additional information on altitude cruise conditions.

()

28. Critical altitude mixture control runs, made at normal and military powers, and at sea-level and high gear minimum slip conditions, are shown on Plate 27. Standard altitude conditions were maintained at the F4U-5 airplane auxiliary stage entrance ducts, and carburetor air temperatures were controlled by the F4U-5 intercoolers to approximately 90°F. Standard altitude exhaust pressure was maintained at the outlets of the F-47N type exhaust collector and approximately 480°F cylinder head temperatures were employed. The engine was operated without the manifold pressure regulator. Manifold pressure requirements at take-off and normal rated powers at sea-level will be slightly higher (see Paragraph 2) with the Stromberg CO+3F regulator installed because the engine would be operating with a controlled throttle drop; however, critical altitude runs will be the same because full throttle and minimum slip high gear is attained in both cases. These data indicate that, at guaranteed SFC's given in reference (b), the engine exceeds its guaranteed critical altitudes by 4100 feet at normal rated power and 2200 feet at military power, minimum slip high gear.

29. Sea-level and altitude overpower runs are shown on Plates 28 to 30, inclusive. Runs were made with "Rich" mixtures as produced by the P.L. No. 390940-10 setting of the PR-64B2 carburetor except at higher air flows, where manual control was necessary (air pressure to carburetor diaphram) to prevent excessive leaning. Standard altitude temperature was maintained at the auxiliary stage entrance ducts and carburetor air temperatures were regulated through the FAU-5 airplane type intercoolers to give intercooler effectiveness ratios of 68 per cent at sea-level, 64 per cent from 20 to 30,000 feet, and 61 per cent from 30 to 40,000 feet, AN-F-48 (115/145) grade fuel was used throughout, and manifold pressures at sea-level and critical altitude were increased until limited by incipient detonation. Also plotted on these plates are data from an overspeed run (2900 rpm) at take-off power, sea-level, which indicates the effects of increased engine rpm on manifold pressure, air flow, etc., requirements.

~2

30. Plates 31 to 34, inclusive, show altitude characteristics and hysteresis checks of the Stromberg CO-3F Automatic Manifold Pressure Regulator (No. B-10077, P.L. No. 3909433) at normal rated and military speeds. These runs were made with the Stromberg PR-64B2 carburetor in the "Normal" mixture position (P.L. No. 390940-10), with standard altitude temperatures at the auxiliary stage entrance ducts, and standard altitude pressures at the outlets of the F-47N airplane-type exhaust collector. Carburetor air temperatures were controlled by the F4U-5 airplane intercoolers to agree with intercooler effectiveness ratios shown on curves. A constant setting of the manifold pressure regulator (set at sea-level) was maintained throughout these runs and the altitude was varied in successive steps from sea-level to above the critical altitude and then returned to sea-level. Operation of the control was satisfactory and the regulation of manifold pressure was within ±1 in. Hg for the two runs made, Considerable surging was encountered when the control shifts the couplings from low to high (and reverse) and at the point just below the critical where the carburetor throttles are fully opened, However, this surging may not be encountered in the airplane installation (F4U-5) to as great a degree since a constant inlet pressure is maintained at the auxiliar, stage entrance ducts. In the dynamometer installation, auxiliary stage altitude was controlled by a butterfly-type throttling valve. As the altitude was increased by throttling the air-flow to the entrance ducts, the point was reached where the control supplied oil to the high coupling, (momentarily changing the impeller speed) which in turn varied the air flow. This variation changed the entrance pressure, and before the butterfly altitude valve could be changed (automatic or manual), a surging condition was encountered,

31. Minimum mixture characteristics of the engine in neutral, low and high gears at sea-level and altitude are presented on Plates 35 and 36. Plate 35 shows sea-level mixture control runs at cruise speeds using neutral and partial auxiliary low ratios (near maximum slip) and includes various check points with colder carburetor air and cylinder head temperatures. Plate 36 shows runs with varying carburetor air and cylinder head temperatures for minimum slip operation in low and high auxiliary blower using the automatic manifold pressure regulator, These runs were made at higher airflows and speeds than would normally be required for high altitude operation because auxiliary stage supercharger stalling was encountered at lower cruise conditions. Spotted on the curves are the "Normal" mixture limits of the P.L. No. 390940-10 setting of the PR-64B2 carburetor, These data indicate that, throughout the range tested, satisfactory engine operation can be obtained at mixtures considerably below the carburetor setting when using BG-RB19R spark plugs, and a considerable saving in fuel could be obtained if the "Normal" mixture setting was made leaner.

These data indicate that operation with grade (115/145) fuel is satisfactory throughout the engine operating range. AN-F-48 (100/130) grade fuel is not recommended for use with this engine at military speed unless the power is lowered to a value below 2200 bhp at sea-level and below 1590 bhp at the critical altitude. An unusual occurrence was noted with this engine at military speed at both sea-level and the critical altitude; namely, an increase in mixture strength above certain values resulted in a decrease in detonation-limited brake horsepower. This may be attributed to the fact that as the fuel-air ratio is increased (above maximum power) more auxiliary stage supercharging is necessary to compensate for the power lost by richened mixtures, and this in turn increases the friction horsepower and indicated mean effective pressures. A point is evidently reached where the anti-knock tendency afforded by the increased mixture strength is counterbalanced and overcome by the increased IMEP, resulting in a decreased detonation-limited brake horsepower. Cruising power runs at sea-level and altitude

- 17 -

are also shown on these plates. These data indicate that operation would be satisfactory throughout with (115/145) grade fuel as no detonation could be obtained at these cruise conditions. AN-F-48 (100/130) grade fuel also provided satisfactory detonation-free operation at cruise speed and power loading conditions.

33. Engine and air box carburetor characteristics are shown on Plates 39 and 40. The Stromberg PR-64B2 carburetor, No. 729821 incorporating the P.L. No. 390940-10 setting, was used for these checks, and this carburetor was used throughout the entire calibration. Pratt and Whitney acceptance limits are also plotted on Plate 39, and show that the carburetor metering was well within these limits. These data also show that altitude compensation of the carburetor was satisfactory. Mixture control runs and detonation-limited mixture response runs, discussed in the preceding paragraphs and plotted on Plates 35 to 38, inclusive, indicate that satisfactory cruise operation was obtained at leaner mixtures, and the cruise range could be extended to a higher airflow before enrichment was necessary. It is therefore suggested that the possibility of lowering the cruise normal mixture limits to values nearer best economy and increasing the cruise operating airflow range be considered.

34. Plate 41 is a correction curve for carburetor air temperature deviation from standard temperature and a correction curve for mixture temperature deviation from the plotted calibration values. These curves are derived from various runs at different powers made with constant manifold pressure, fuel-air ratio, and cylinder head temperatures (for each run) and combined to give a percentage power correction.

35. Auxiliary stage inlet temperature correction curves at sea-level and the critical altitude are plotted on Plate 42. Various speeds were run and combined to obtain these curves and all inlet conditions to the cylinders were maintained constant; that is, constant fuel-air ratio, mixture temperature, manifold pressure and cylinder head temperature for each run. The data show that for critical altitude operation with minimum slip, high blower, where cold auxiliary stage inlet temperatures prevail, there is no power correction necessary for temperature variation through the auxiliary stage. For auxiliary stage operation at sea-level however, there should be a slight correction for temperature effects on auxiliary stage power requirements as indicated on the curve. It is believed that this increase in power requirements with hotter air at the auxiliary superchargers, or to higher supercharging requirements for the same mass airflow with the hotter air there by increasing the auxiliary supercharger friction and pumping horsepower.

36. Plates 43 and 44 show the exhaust back pressure correction curves in neutral gear, sea-level, and at minimum slip, high blower conditions, critical altitude. For each run, the inlet conditions, to the cylinders (manifold pressure and temperature and fuel-air ratio) were maintained constant and the exhaust pressure varied to change the Pe/Pm ratio (exhaust pressure to manifold pressure). At minimum slip, high gear conditions, speeds below 2000 rpm could not be run because of auxiliary stage impeller stalling. It is interesting to note that at these high gear conditions, the percentage power correction for speeds from 2000 to 2800 rpm is the same, based on Pe/Pm ratios.

- 18 -

ŝ

37. Plate 45 shows the effect of cylinder head temperature on bhp at low gear military, normal, and two cruise speeds. Inlet conditions to the cylinders were maintained constant throughout each run (fuel-air ratio, manifold pressure and temperature).

)

7, 44

38. Cruise stability operating limits of the engine with and without the auxiliary stage "bleed-off" valve are shown on Plate 46. Plate 47 is an additional plot showing the approximate altitudes at which stalling was encountered. The Stromberg CO-3F Automatic Manifold Pressure Regulator was set at sea-level and the engine speed held constant. The altitude was then raised gradually to above the critical altitude and returned to sea-level, noting any stalling tendencies of the auxiliary impellers. A surging condition was generally encountered before stall, and was accompanied by a high amplitude, low frequency vibration, Complete stall was readily ascertained by a sudden rise in temperature at the auxiliary stage entrance screen of the stalled impeller. Temperatures in excess of 240°F have been measured on this screen. The greatest tendency toward supercharger stalling was noted while descending in altitude near the critical altitude when the supercharger slows down in shifting from minimum to maximum slip high gear and also from maximum slip high to minimum slip low gear. In practically all cases, the right hand impeller was the one that stalled. The auxiliary stage "bleed-off" valve prevented supercharger stalling at certain conditions, but high gear operation is still restricted. The following table lists rpm and manifold pressure combinations that should be used for high altitude cruise operation with the "bleed-off" valve:

:Altitude	:		· · · · ·	Recom	mended AS	RP at Given RD	Ŵ :

* Stalling occasionally encountered, particularly when decreasing altitude at near coupling change conditions. Also encountered at low manifold pressures when going into Aux. Low.

It was found that the best method for getting out of stall was to rapidly increase rpm and manifold pressure. However, a serious power and speed surge was encountered in the dynamometer installation when this method was employed and the stalled impeller suddenly returned to full pumping capacity. It is believed the surge would be considerably less in the airplane (F4U-5) because of the faster action of the propeller speed regulation. Verbal contact with a representative of Squadron VX-3 NAS, Atlantic City, in regards to high altitude auxiliary stage supercharger pulsation in the F4U-5 airplane, indicated trouble was encountered at similar operating conditions as the dynamometer engine, and the best method to get out of stall was to increase engine rpm. References (i) and (j) present additional information on this subject.

39. Plate 48 shows auxiliary stage overall performance characteristics of the R-2800-32W engine, No. P-28802. These runs were made with both auxiliary superchargers exhausting to atmosphere. Each of the dual superchargers was tested separately; airflow through the test supercharger was controlled by a butterfly-type altitude regulating valve, the other auxiliary supercharger being open to atmosphere. The engine was run at the speeds shown using the full high ratio (minimum slip) of the auxiliary stage (9.65 to 1). Data plotted show pressure ratio (across each auxiliary supercharger) vs. Qc/1000, Following is a list of symbols and definitions used.

> $Q_0 = Equivalent inlet volume airflow, <math>Q/\sqrt{6}$ Q = Inlet airflow, cu. ft./min. = $\frac{0.0126 \text{ WT1}}{P_{1T}}$

• = Temperature correction factor = T1/518.6

W - Meight airflow = K $\int \frac{Pa}{T}$, Lb./Hr.

 $T_1 = Inlet temperature, °R.$

 P 1T = Inlet pressure, total

<u>(</u>)

1)

Similar data from Pratt and Whitney supercharger performance curves (see reference (i)) indicated auxiliary impeller stall points were in good agreement between the two sets of data. Corrected airflow curves of the engine, when spotted on these curves, indicate that the auxiliary superchargers are operating at near stall conditions at high altitude, low speeds, and manifold pressures. However, the purpose of the auxiliary stage bleed-off valve is to dump a portion c of the air (approximately 3%) overboard after it has been compressed by the dual auxiliary impellers (a wasteful process because of the higher SFC's encountered), and thus keep the dual stages operating at a higher capacity and above the stall limit line. The auxiliary impellers are therefore pumping slightly more air than is being used by the engine (values plotted on calibration curves). The

20 -

performance curves plotted indicate that the two dual superchargers were not equally matched and the left hand supercharger developed a higher pressure ratio, for a given impeller speed, than the right supercharger. Therefore, as the outlets operate at the same pressure (carburetor top deck) and inlets are at airplane altitude, there is an unbalance between the two superchargers and it is doubtful whether they will divide the load equally. It is believed the supercharger operating at the lower pressure ratio will tend to reduce airflow in an effort to balance exit pressures, and as the curves are relatively flat in this operating range, will go into stall. In nearly all cases where unstable operation occurred during the calibration, stalling was noted at the low output (right) impeller.

40. Plates 49 and 50 show the altitude friction characteristics of the engine at the same operating conditions as the "normal" altitude calibration, Because of horsepower limitations of the dynamometer (approximately 620 bhp) it. was necessary to estimate normal and military rpm friction at powers above this value. Since operation was in auxiliary stage at these conditions, estimations were based on additional power requirements of the auxiliary stage (on a temperature rise and weight airflow basis) and oil heat rejection characteristics. Friction horsepower (difference between indicated horsepower and brake horsepower) is considered the sum of the horsepower absorbed by both superchargers, the mechanical friction of the engine, and the pumping action of the pistons. Since the engine was not operating at the same temperature at which it would operate when firing, there was probably some error in simulating both the mechanical friction (effect of temperature upon bearing clearances, oil viscosity, etc.) and the pumping horsepower (improper valve timing and incorrect temperature of the air flowing through the cylinders). However, since the horsepower absorbed by the superchargers of this type engine constitutes the greatest portion of the friction horsepower, the values plotted should be a close approximation. Friction losses at high gear, auxiliary stage were extremely high and accounts for the high specific fuel consumptions encountered at these conditions. As an example, at high gear military power critical, the engine was actually developing over 2900 bhp but only 1800 bhp was being delivered to the propeller shaft for useful output.

41. Plate 51 is a plot of oil flow and heat rejection characteristics of the engine at propeller load powers, sea-level. These data show that the engine exceeds the guaranteed oil flow limits (see reference (b)) at military speed, and that oil flow and heat rejection at normal rated speed are marginal. Oil flow and heat rejection of the engine with the CO-3F Automatic Manifold Pressure Regulator in operation are somewhat higher than without it because a controlled throttle drop is maintained for all altitudes below the critical.

42. Plate 52 is a comparison of brake horsepower output of the engine as determined by the engine torquemeter and by the dynamometer. The constant of 158.3 checked dynamometer determined power well within ± 2 per cent.

AEL-1122

H3. Plate 53 shows a sketch of the induction system used for the calibration. Plate 54 is a photograph of the main accessory drive shaft failure on the first calibration engine, YR-2800-32%, No. P-28015. Plates 55 and 56 show photographs of No. 8 piston failure and the mating cylinder of Pratt and Whitney R-2800-32^W engine, No. P-28802. Plates 57 and 58 are photographs of the engine installed in the dynamometer room, and Plates 59 to 61, inclusive, show general views of the engine.
