AERONAUTIC SYMBOLS

1. FUNDAMENTAL AND DERIVED UNITS

	Symbol	Metric		English	
		Unit	Abbreviation	Unit	Abbreviation
Length	l	meter	m	foot (or mile)	ft (or mi)
Time	t	second	s	second (or hour)	sec (or hr)
Force	F	weight of 1 kilogram	kg	weight of 1 pound	lb
Power	P	horsepower (metric)		horsepower	hp
Speed	V	kilometers per hour	kph	miles per hour	mph
		meters per second	mps	feet per second	fps

2. GENERAL SYMBOLS

W Weight $=mg$

Standard acceleration of gravity $=9.80665$ m/s^2 or 32.1740 ft/sec^2

m Mass $=\frac{W}{g}$

I Moment of inertia $=mk^2$. (Indicate axis of radius of gyration k by proper subscript.)

Coefficient of viscosity

ν Kinematic viscosity

ρ Density (mass per unit volume)

Standard density of dry air, 0.12497 kg-m^{-4}-s^2 at 15° C and 760 mm; or 0.002378 lb-ft^{-4} sec^2

Specific weight of "standard" air, 1.2255 kg/m^3 or 0.07651 lb/cu ft

3. AERODYNAMIC SYMBOLS

S Area

S_w Area of wing

G Gap

Span

Chord

A Aspect ratio, $\frac{b^2}{S}$

V True air speed

Dynamic pressure, $\frac{1}{2}\rho V^2$

L Lift, absolute coefficient $C_L=\frac{L}{qS}$

D Drag, absolute coefficient $C_D=\frac{D}{qS}$

D_0 Profile drag, absolute coefficient $C_{D_0}=\frac{D_0}{qS}$

D_i Induced drag, absolute coefficient $C_{D_i}=\frac{D_i}{qS}$

D_p Parasite drag, absolute coefficient $C_{D_p}=\frac{D_p}{qS}$

C Cross-wind force, absolute coefficient $C_C=\frac{C}{qS}$

i_w Angle of setting of wings (relative to thrust line)

i_t Angle of stabilizer setting (relative to thrust line)

Q Resultant moment

Ω Resultant angular velocity

R Reynolds number, $\rho\frac{Vl}{\mu}$ where l is a linear dimension (e.g., for an airfoil of 1.0 ft chord, 100 mph, standard pressure at 15° C, the corresponding Reynolds number is 935,400; or for an airfoil of 1.0 m chord, 100 mps, the corresponding Reynolds number is 6,865,000)

α Angle of attack

ϵ Angle of downwash

α_0 Angle of attack, infinite aspect ratio

α_i Angle of attack, induced

α_a Angle of attack, absolute (measured from zero-lift position)

γ Flight-path angle

National Advisory Committee for Aeronautics

Headquarters, 1500 New Hampshire Avenue NW, Washington 25, D. C.

Created by act of Congress approved March 3, 1915, for the supervision and direction of the scientific study of the problems of flight (U. S. Code, title 49, sec. 241). Its membership was increased to 15 by act approved March 2, 1929. The members are appointed by the President, and serve as such without compensation.

REPORT No. 837

STANDARD NOMENCLATURE FOR AIRSPEEDS WITH TABLES AND CHARTS FOR USE IN CALCULATION OF AIRSPEED

By William S. Aiken, Jr.

SUMMARY

Symbols and definitions of various airspeed terms that have been adopted as standard by the NACA Subcommittee on Aircraft Structural Design are presented. The equations, charts, and tables required in the evaluation of true airspeed, calibrated airspeed, equivalent airspeed, impact and dynamic pressures, and Mach and Reynolds numbers have been compiled. Tables of the standard atmosphere to an altitude of 65,000 feet and a tentative extension to an altitude of 100,000 feet are given along with the basic equations and constants on which both the standard atmosphere and the tentative extension are based.

INTRODUCTION

In analyses of aerodynamic data very often wind-tunnel or flight measurements must be converted into airspeed and related quantities that are used in engineering calculations. Attempts to accomplish such conversion by use of available methods have been complicated by the diversity of symbols and definitions and by the necessity of referring to equations, charts, and tables from a number of different sources. A standard set of symbols and definitions of various airspeed terms that were adopted by the NACA Subcommittee on Aircraft Structural Design and a compilation of the necessary equations, charts, and tables for converting measured pressures and temperatures into airspeeds, determining Mach numbers and Reynolds numbers, and determining other quantities such as dynamic and impact pressures that are of interest are therefore presented herein.

In the preparation of the present paper, results that have been included in previous papers have been extended to include higher altitudes and quantities not given in the previous papers, since recent requests have indicated the need for such an extension of standard-atmosphere tables.

The tables and figures have been arranged for ease in determination of the airspeed, which is usually based on the interpretation of measurements of differential pressures obtained with some pitot-static arrangement. The interrelation of the various airspeed quantities is independent of the method used in the measurement. Instrument and installation errors have been assumed to have been taken into account.

STANDARD SYMBOLS AND DEFINITIONS

At the November 1944 meeting of the NACA Subcommittee on Aircraft Structural Design, representatives from the Army, Navy, CAA, NACA, and several aircraft manufacturers adopted as standard the following symbols and definitions for airspeeds:

V true airspeed

V_i indicated airspeed (the reading of a differential-pressure airspeed indicator, calibrated in accordance with the accepted standard adiabatic formula to indicate true airspeed for standard sea-level conditions only, uncorrected for instrument and installation errors)

V_c calibrated airspeed (the airspeed related to differential pressure by the accepted standard adiabatic formula used in the calibration of differential-pressure airspeed indicators and equal to true airspeed for standard sea-level conditions)

V_e equivalent airspeed ($V\sigma^{1/2}$)

Use of equivalent airspeed in combination with various subscripts is customary, particularly in structural design, to designate various design conditions. It is suggested that the foregoing symbols be retained intact when further subscripts are necessary.

Most of the following symbols, which are used herein, have already been accepted as standard and are used throughout aeronautical literature. The units given apply to the development of the equations in the present report.

V	true airspeed, feet per second
V_c	calibrated airspeed, feet per second
V_e	equivalent airspeed, feet per second
a	speed of sound in ambient air, feet per second
M	Mach number (V/a)
ρ	mass density of ambient air, slugs per cubic foot
ρ_0	standard mass density of dry ambient air at sea level, 0.002378 slug per cubic foot
σ	density ratio (ρ/ρ_0)
q	dynamic pressure, pounds per square foot $\left(\frac{1}{2}\rho V^2\right)$
q_c	impact pressure, pounds per square foot (total pressure minus static pressure p)
p	static pressure of free stream, pounds per square foot
p_0	static pressure of free stream under standard sea-level conditions, pounds per square foot
t	temperature, °F or °C
Δt	difference between free-air temperature and temperature of standard atmosphere, °F

T absolute temperature, °F absolute or °C absolute
T_{std} standard-atmosphere free-air temperature, °F absolute
T_0 standard sea-level absolute temperature, 518.4 °F absolute
T_m harmonic mean absolute temperature, °F absolute (defined in equation (B5))
f compressibility factor defined in equation (11)
f_0 compressibility factor defined in equation (16)
γ ratio of specific heat at constant pressure to specific heat at constant volume (assumed equal to 1.4 for air)
h absolute altitude, feet
h_p pressure altitude, feet
g acceleration of gravity, 32.1740 feet per second per second
m modulus for common logarithms, $\log_{10} e$ (0.434294)
μ coefficient of viscosity, slugs per foot-second
ν kinematic viscosity, square feet per second (μ/ρ)
R Reynolds number $\left(\rho \frac{Vl}{\mu}\right)$
R_{std} Reynolds number for standard atmospheric conditions
l characteristic length, feet

CALCULATION OF AIRSPEED AND RELATED QUANTITIES

Because pitot-static arrangements are used as the basis for the determination of airspeed, aeronautical engineering practice has developed to include the use of a number of airspeed terms and quantities, each of which has a particular field of usefulness. True airspeed is principally of use to aerodynamicists, and indicated and calibrated airspeeds are principally of use to pilots. Equivalent airspeed is used by structural engineers, since all load specifications have long been based on this quantity.

Definite relationships exist between true airspeed, Mach number, Reynolds number, calibrated airspeed, and equivalent airspeed, and all these quantities may be related either to the dynamic pressure q or to the impact pressure q_c. Some of the relations presented herein apply to the calculation of true airspeed and Mach number from airspeed measurements obtained with an airspeed indicator of standard calibration. Other relations apply to the calculation of true airspeed when the impact pressure is measured directly.

If it is assumed that the total-head tube and the static-head tube measure their respective pressures correctly and that these tubes are connected to an appropriate instrument, the impact pressure measured is given by the adiabatic equation when $V<a$:

$$q_c=p\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho}{p}V^2\right)^{\frac{\gamma}{\gamma-1}}-1\right] \qquad (1)$$

Standard airspeed indicators used in Army and Navy airplanes since 1925 have been calibrated according to equation (1) for standard sea-level conditions; that is, according to the equation when $V<a$,

$$q_c=p_0\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho_0}{p_0}V_c^2\right)^{\frac{\gamma}{\gamma-1}}-1\right] \qquad (2)$$

where the subscript 0 denotes standard sea-level conditions and V_c is the calibrated airspeed. The calibrated airspeed is, therefore, equal to true airspeed only for standard sea-level conditions.

DETERMINATION OF TRUE AIRSPEED FROM CALIBRATED AIRSPEED

The formula that relates the true airspeed to the calibrated airspeed may be found by equating the right-hand terms of equations (1) and (2) as follows:

$$p\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho}{p}V^2\right)^{\frac{\gamma}{\gamma-1}}-1\right]=p_0\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho_0}{p_0}V_c^2\right)^{\frac{\gamma}{\gamma-1}}-1\right] \qquad (3)$$

Because the exact numerical solution of equation (3) for true airspeed is involved and requires a great deal of time, a number of charts for the determination of the true airspeed from the calibrated airspeed for various atmospheric conditions have been derived. (See references 1 to 3.) A typical chart (taken from reference 1) that shows the relationship between Mach number, calibrated airspeed, pressure altitude, temperature, and true airspeed is given in figure 1. This chart is widely used because of its convenience. Airspeed may be obtained from this chart with an accuracy within 2 miles per hour when standard conditions hold and when values of airspeed and pressure altitude explicitly given by the chart are chosen; the possible errors increase to within 5 miles per hour, however, when the temperature conditions are not standard and when interpolation is required for both altitude and airspeed.

For some purposes, charts such as figure 1 are not sufficiently accurate. A series of logarithmic tables that may be used to determine the true airspeed in knots from observed values of calibrated airspeed, pressure altitude, and free-air temperature is given in reference 4. Logarithmic tables of the type given in reference 4 are of limited usefulness since they cannot be used conveniently to evaluate the intermediate quantities (impact pressure and Mach number) that are involved in the computation of true airspeed.

A series of tables (tables I to V) is given in the present report to permit determination of impact pressure q_c in pounds per square foot, Mach number M, and true airspeed V in miles per hour or knots for observed values of V_c in miles per hour or knots, pressure altitude h_p in feet, and temperature in degrees Fahrenheit or Centigrade. The accuracy of the tables is far greater than that with which experimental data can normally be obtained. With ordinary care in interpolation, errors should be less than 0.25 mile per hour throughout the greater part of the airspeed and altitude ranges.

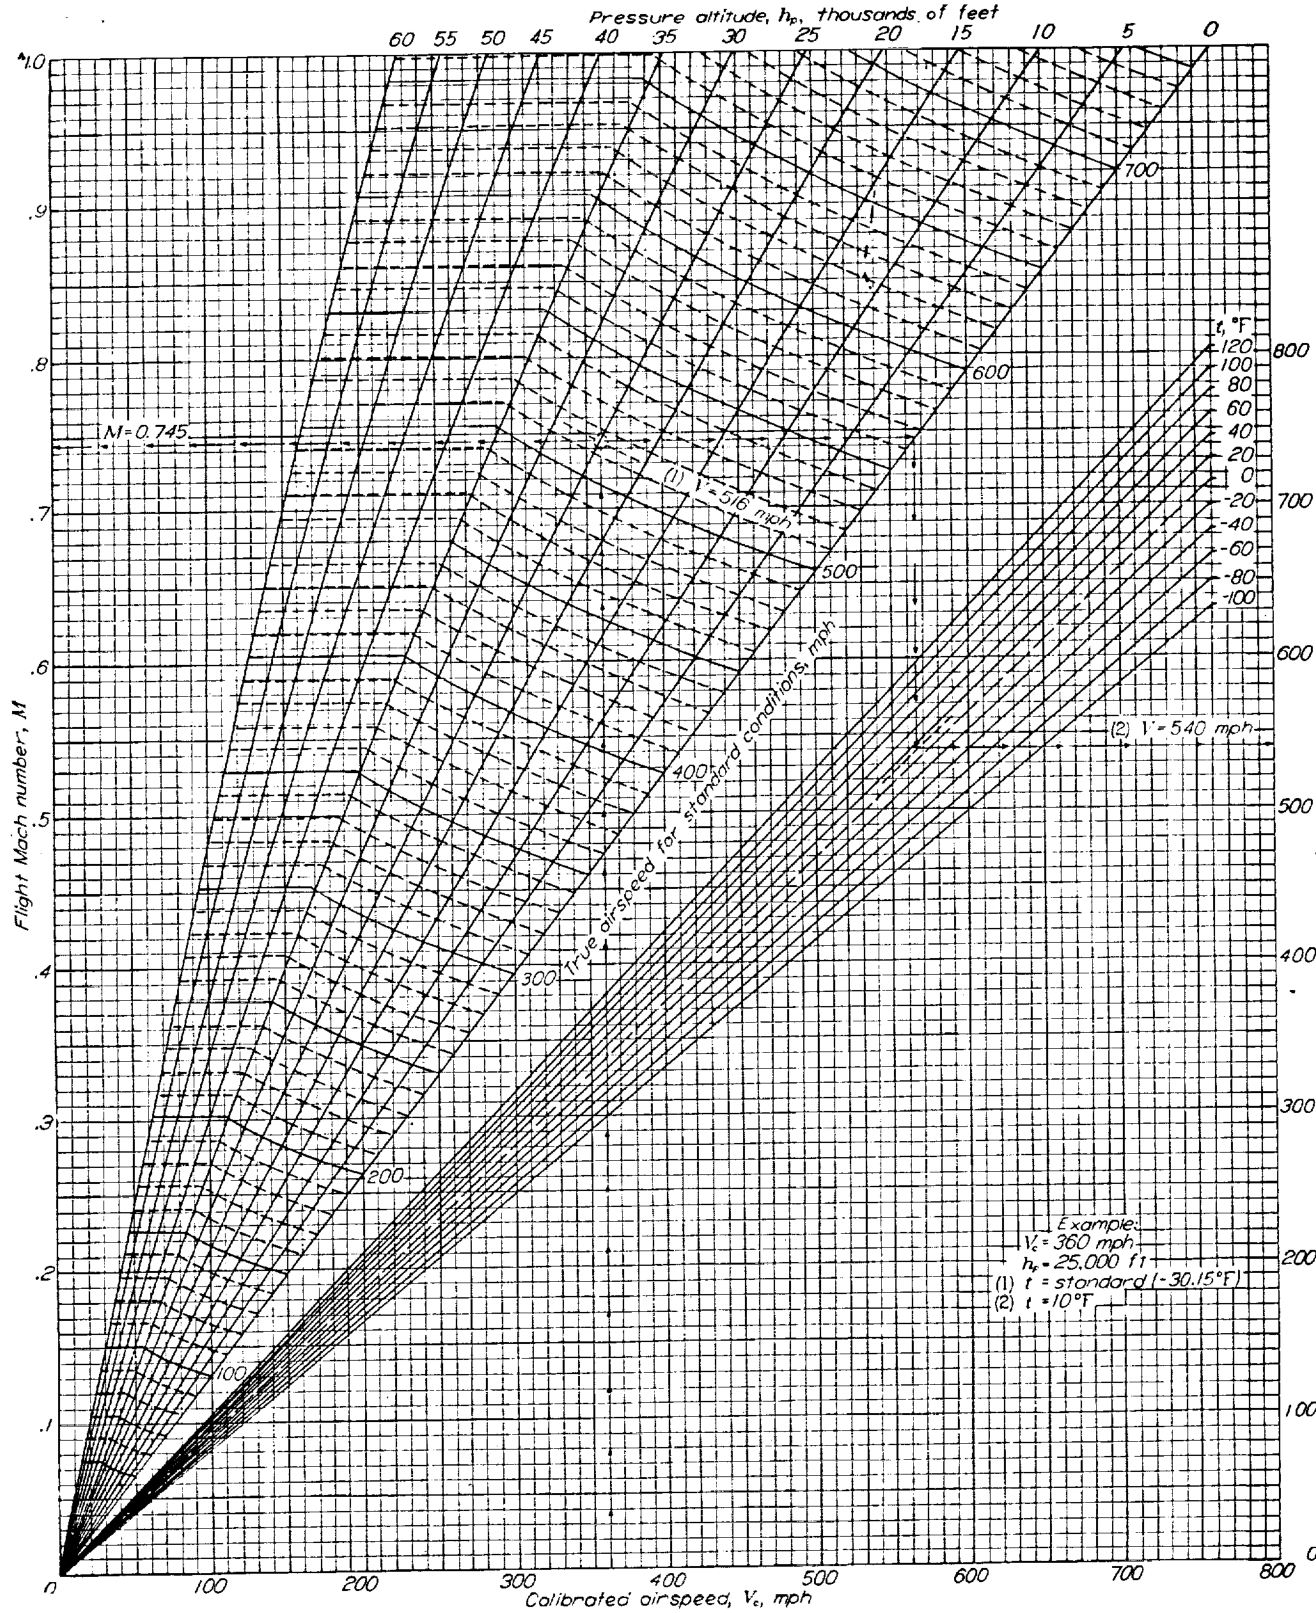

FIGURE 1.—Chart of airspeed against Mach number. (From reference 1.) Airspeed indicator is assumed to be calibrated to read true airspeed for standard sea-level conditions.

Table I, which gives values of impact pressure q_c in pounds per square foot for values of V_c in miles per hour, was computed directly from equation (2); standard values were used for all the constants occurring in this equation. Table II gives values of impact pressure q_c in pounds per square foot for values of V_c in knots. In computing the values of q_c in table II, the conversion from feet to nautical miles used was as follows:

1 nautical mile=6080.2 feet

Tables I and II give the impact pressures for V_c in increments of 1 mile per hour and 1 knot for speeds corresponding to Mach numbers at sea level from 0 to 1.000.

Table III gives values of static pressure p in pounds per square foot for various values of pressure altitude h_p from −1,000 to 60,000 feet in increments of 100 feet and from 60,000 to 100,000 in increments of 1,000 feet for standard atmospheric conditions. (The use of the term "standard atmosphere" throughout this report includes values for the standard atmosphere up to an altitude of 65,000 feet and for the tentative extension of the standard atmosphere from 65,000 to 100,000 feet.) The values given in table III were computed from the equation

$$h_p=\frac{p_0}{\rho_0 gm}\frac{T_m}{T_0}\log_{10}\frac{p_0}{p} \tag{4}$$

which is given as equation (4) of reference 5 with slightly different symbols.

From tables I or II and III the ratio of impact pressure to static pressure q_c/p may be established and the Mach number, which is a function of this ratio, may then be found. The relation between Mach number and q_c/p may be found from equation (1) as

$$M=\left\{5\left[\left(\frac{q_c}{p}+1\right)^{2/7}-1\right]\right\}^{1/2} \tag{5}$$

Table IV gives values of Mach number for various values of the ratio q_c/p.

The Mach number M is defined as the ratio of the true airspeed to the speed of sound in ambient air and thus, with the Mach number determined, the true airspeed may be found by the use of

$$V=Ma \tag{6}$$

The speed of sound in ambient air is found from the equation

$$a=\sqrt{\gamma\frac{p}{\rho}} \tag{7}$$

which may be rewritten in the following forms when the value of γ is assumed equal to 1.4 and the air is assumed to follow the gas law

$$\rho=\rho_0\frac{p}{p_0}\frac{T_0}{T}$$

If a is in miles per hour and T is in degrees Fahrenheit absolute

$$a=33.42\sqrt{T} \tag{8}$$

If a is in knots and T is in degrees Fahrenheit absolute

$$a=29.02\sqrt{T} \tag{8a}$$

If a is in miles per hour and T is in degrees Centigrade absolute

$$a=44.84\sqrt{T} \tag{8b}$$

If a is in knots and T is in degrees Centigrade absolute

$$a=38.94\sqrt{T} \tag{8c}$$

Table V gives the speed of sound for values of free-air temperature in degrees Fahrenheit, and table VI gives the speed of sound for temperatures in degrees Centigrade. Tables V and VI give the speed of sound both in miles per hour and in knots.

In order to illustrate the use of tables I to VI to determine the true airspeed from calibrated airspeed, the following example is presented:

Given:

Calibrated airspeed V_c=398 miles per hour

Pressure altitude h_p=22,000 feet

Temperature t=−12° F

To find:

True airspeed V in miles per hour

Step (1)

From table I, for V_c=398 miles per hour,

q_c=433.7 pounds per square foot

Step (2)

From table III, for h_p=22,000 feet,

p=893.3 pounds per square foot

Step (3)

From these values,

$$\frac{q_c}{p}=\frac{433.7}{893.3}=0.4855$$

Step (4)

From table IV, for $\frac{q_c}{p}=0.4855$,

M=0.7736

Step (5)

From table V, for t=−12° F,

a=706.9 miles per hour

Step (6)

By use of equation (6),

$V=Ma=0.7736\times706.9$ miles per hour

=546.8 miles per hour

DETERMINATION OF TRUE AIRSPEED FROM IMPACT PRESSURE

In order to convert measurements of impact pressure to true airspeed, the static pressure and the speed of sound must be known. It is convenient first to determine the Mach number from measurements of the impact pressure and the static pressure. Table IV may be used to find the Mach number from the ratio q_c to p and tables V and VI may be used to find the speed of sound for various values of the free-air temperature. The true airspeed may then be determined from equation (6).

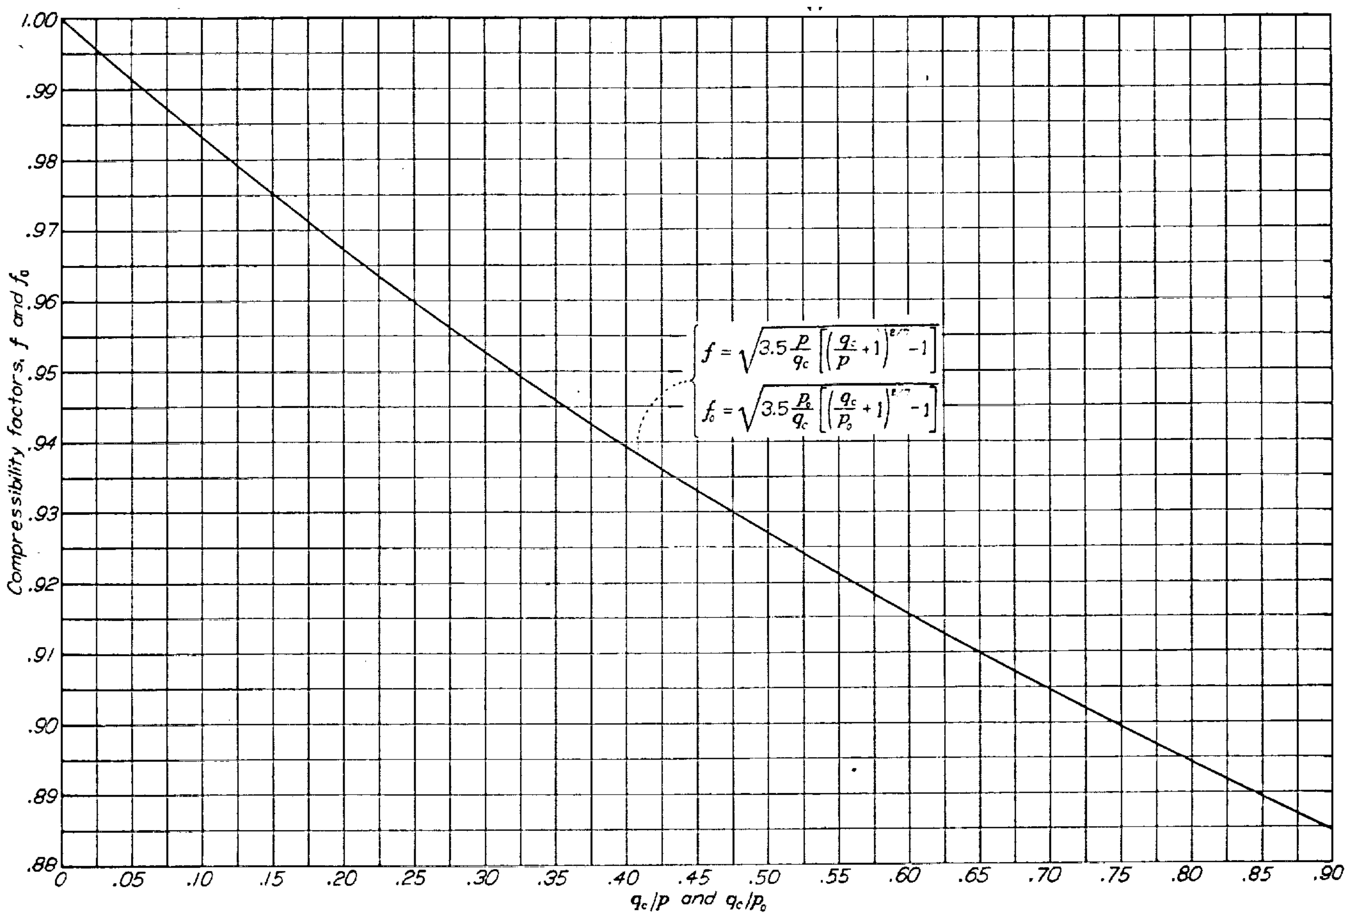

FIGURE 2.—Compressibility factors.

DETERMINATION OF DYNAMIC PRESSURE AND EQUIVALENT AIRSPEED

In order to reduce flight-test data to coefficient form or to demonstrate compliance with certain structural requirements, either the dynamic pressure q or the equivalent airspeed V must be determined. The relations of dynamic pressure and equivalent airspeed to impact pressure, static pressure, calibrated airspeed, and Mach number are therefore presented.

Since the dynamic pressure q is by definition

$$q=\frac{1}{2}\rho V^2 \tag{9}$$

it may be expressed as a function of the impact pressure by solving equation (1) for true airspeed and substituting the resultant expression into equation (9), which reduces to

$$q=f^2 q_c \tag{10}$$

where

$$f=\sqrt{\frac{\gamma}{\gamma-1}\frac{p}{q_c}\left[\left(\frac{q_c}{p}+1\right)^{\frac{\gamma-1}{\gamma}}-1\right]} \tag{11}$$

Values of the compressibility factor f are given in figure 2 as a function of q_c/p. The dynamic pressure may also be expressed as a function of Mach number and static pressure from equations (6), (7), and (9) as

$$q=\frac{\gamma}{2}pM^2 \tag{12}$$

Since the equivalent airspeed V_e is by definition

$$V_e=V\sigma^{1/2}=V\sqrt{\frac{\rho}{\rho_0}} \tag{13}$$

the relation between the equivalent airspeed in miles per hour, Mach number, and pressure ratio can be derived from equations (6), (8), (13), and the gas-law equation as

$$V_e=760.9M\sqrt{\frac{p}{p_0}} \tag{14}$$

The variation, determined from equation (14), of equivalent airspeed with Mach number for pressure altitudes from 0 to 100,000 feet is given in figure 3. For convenience, the true airspeed that applies to the standard atmosphere computed from equations (13) and (14) is also included in figure 3.

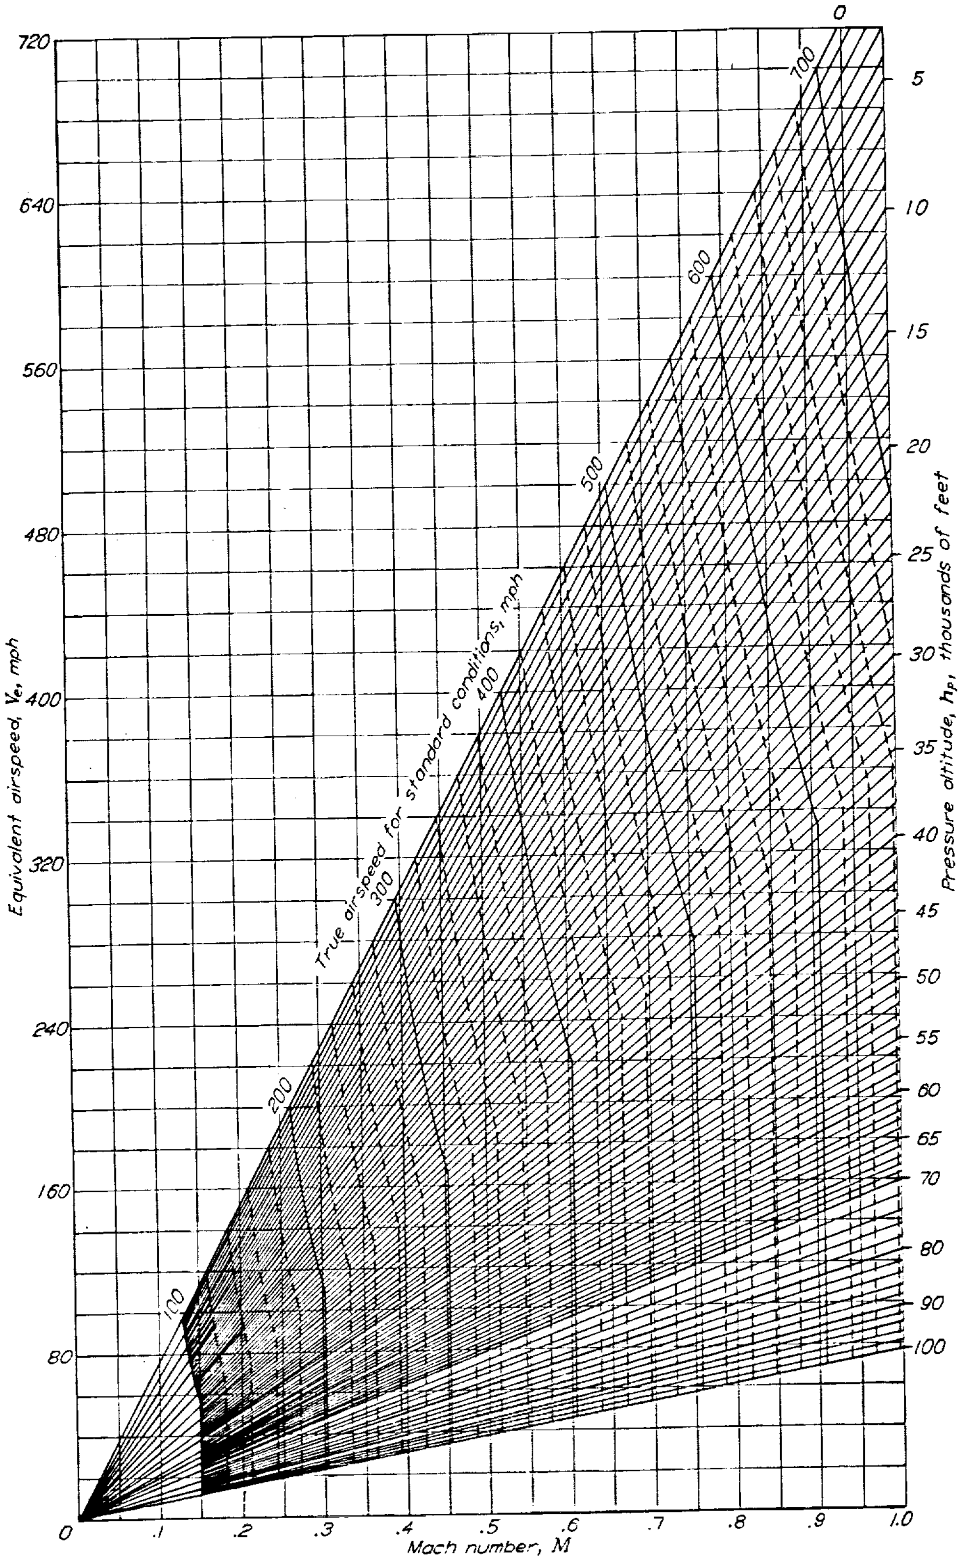

FIGURE 3.—Variation of equivalent airspeed with Mach number and pressure altitude.

Finally, expressions that will relate the true airspeed, the calibrated airspeed, and the equivalent airspeed are determined. If equation (2) is solved for V_c:

$$V_c=\sqrt{\frac{\gamma}{\gamma-1}\frac{p_0}{q_c}\left[\left(\frac{q_c}{p_0}+1\right)^{\frac{\gamma-1}{\gamma}}-1\right]}\sqrt{\frac{2q_c}{\rho_0}} \qquad (15)$$

If

$$\sqrt{\frac{\gamma}{\gamma-1}\frac{p_0}{q_c}\left[\left(\frac{q_c}{p_0}+1\right)^{\frac{\gamma-1}{\gamma}}-1\right]}=f_0 \qquad (16)$$

equation (15) becomes

$$V_c=f_0\sqrt{\frac{2q_c}{\rho_0}} \qquad (17)$$

The compressibility factor f_0 is given in figure 2 as a function of q_c/p_0. Similarly, the true airspeed may be written

$$V=f\sqrt{\frac{2q_c}{\rho}} \qquad (18)$$

From equations (17) and (18)

$$V=V_c\frac{f}{f_0}\sqrt{\frac{\rho_0}{\rho}} \qquad (19)$$

When equations (13) and (19) are summarized

$$V=V_c\frac{f}{f_0}\sqrt{\frac{\rho_0}{\rho}}=V_e\sqrt{\frac{\rho_0}{\rho}} \qquad (20)$$

For convenience, equations relating the various airspeed quantities are listed in appendix A.

DETERMINATION OF REYNOLDS NUMBER

In comparisons of flight and wind-tunnel results charts relating the Reynolds number to the Mach number have been found convenient.

Reynolds number is defined by the formula

$$R=\frac{Vl\rho}{\mu}=\frac{Vl}{\nu} \qquad (21)$$

where l is a characteristic length such as the chord. Equation (21) may be written so that the Reynolds number is expressed as a function of Mach number and absolute temperature in degrees Fahrenheit for unit values of the characteristic length l as

$$\frac{R}{l}=\frac{49.02M\sqrt{T}}{\nu} \qquad (22)$$

In order to facilitate the determination of Reynolds number, figure 4 has been prepared to show the variation of the factor R_{std}/l with Mach number and pressure altitude, where R_{std} is the Reynolds number computed on the basis of the standard atmosphere. Figure 4 (a) holds for pressure altitudes from sea level to 60,000 feet, and figure 4 (b) holds for pressure altitudes from 60,000 to 100,000 feet.

In order to account for free-air conditions other than standard, figure 5 is given to be used in conjunction with figure 4. When $\mu=\frac{2.318}{10^8}\frac{T^{3/2}}{T+216}$ (justification for the use of this equation given in the section entitled "Properties of Standard Atmosphere") is substituted into equation (21), the Reynolds number factor may be written

$$\frac{R}{l}=1.232pM\frac{T+216}{T^2}10^6 \qquad (23)$$

The Reynolds number factor in the standard atmosphere becomes

$$\frac{R_{std}}{l}=1.232pM\frac{T_{std}+216}{T_{std}^2}10^6 \qquad (24)$$

When equation (23) is divided by equation (24)

$$\frac{R}{R_{std}}=\left(\frac{T_{std}}{T}\right)^2\left(\frac{T+216}{T_{std}+216}\right) \qquad (25)$$

Figure 5 gives R/R_{std} as a function of pressure altitude and the deviation Δt of the free-air temperature from standard temperature for a given pressure altitude. In equation form,

$$\Delta t=T-T_{std} \qquad (26)$$

The curves of figure 5 become straight lines for pressure altitudes above 35,332 feet, since T_{std} is constant above this altitude range.

In order to illustrate the procedure to be used in determining Reynolds number, the following example is presented:

Given:

Mach number $M=0.75$
Pressure altitude $h_p=35{,}000$ feet
Characteristic length $l=10$ feet
Deviation of free-air temperature from standard temperature $\Delta t=-10°$ F

To find:

Reynolds number R

Step (1)

From figure 4 (a), for $M=0.75$ and $h_p=35{,}000$ feet,

$$\frac{R_{std}}{l}=1{,}800{,}000 \text{ per foot}$$

Step (2)

For $l=10$ feet,

$$R_{std}=18{,}000{,}000$$

Step (3)

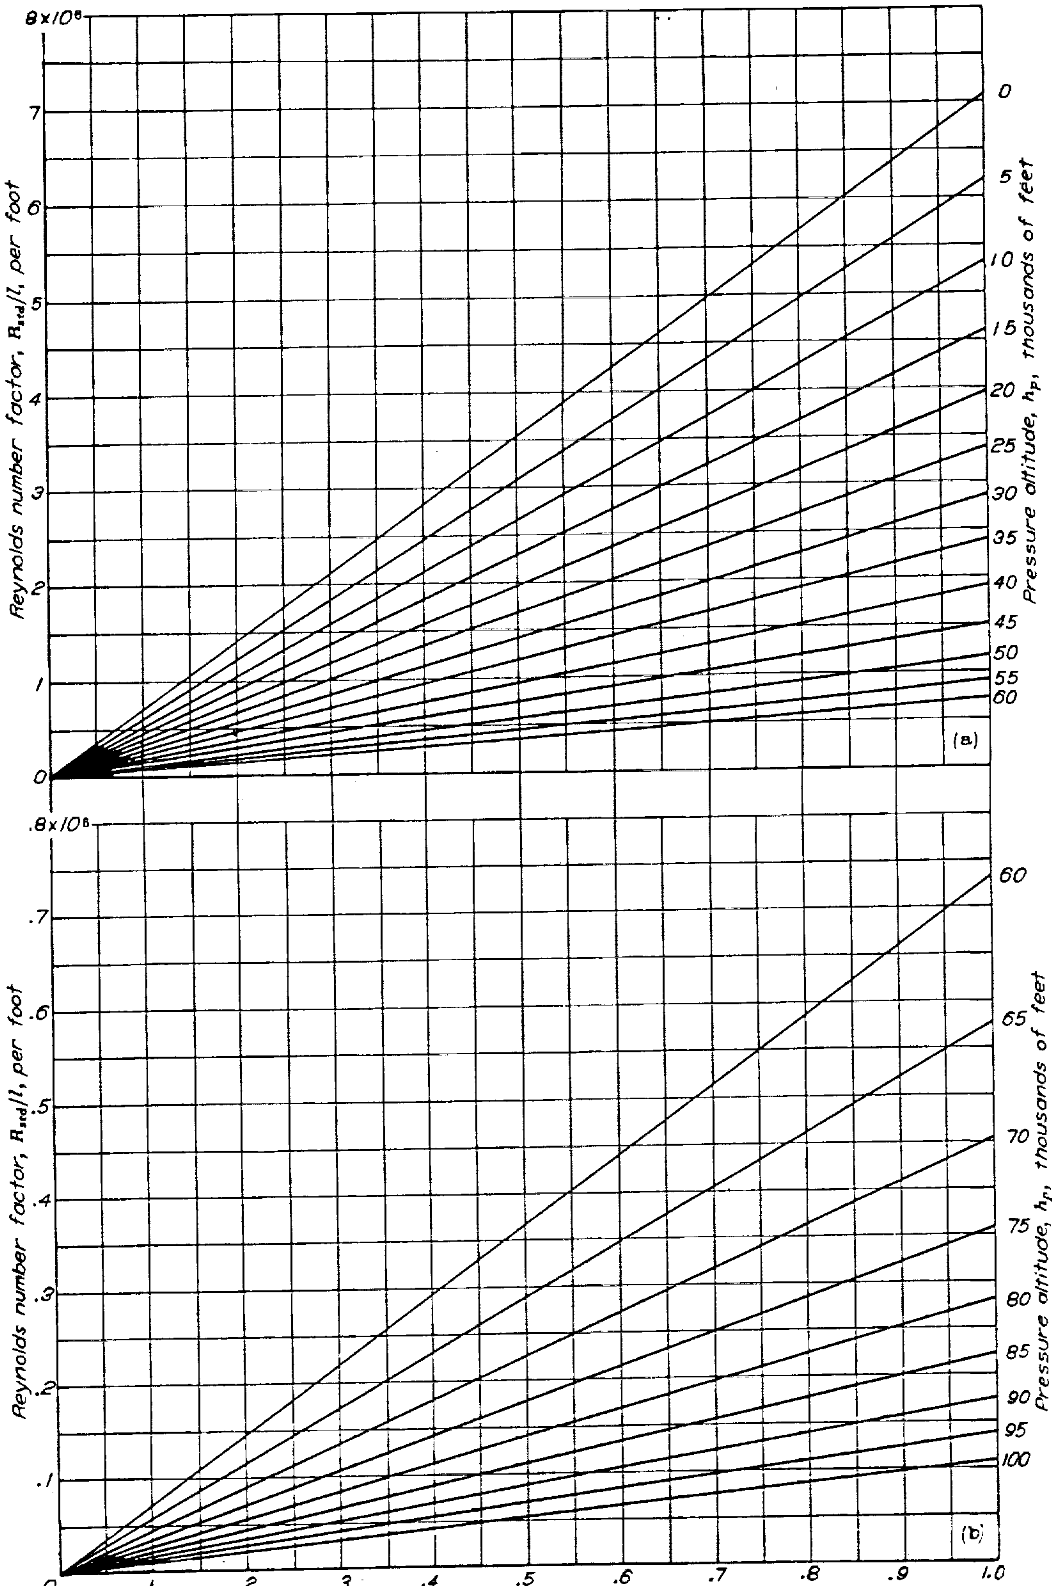
From figure 5, for $h_p=35{,}000$ feet and $\Delta t=-10°$ F,

$$\frac{R}{R_{std}}=1.036$$

Step (4)

From these values,

$$R=18{,}600{,}000$$



(a) Pressure altitudes from 0 to 60,000 feet.

(b) Pressure altitudes from 60,000 to 100,000 feet.

FIGURE 4.—Variation of Reynolds number factor in the standard atmosphere.

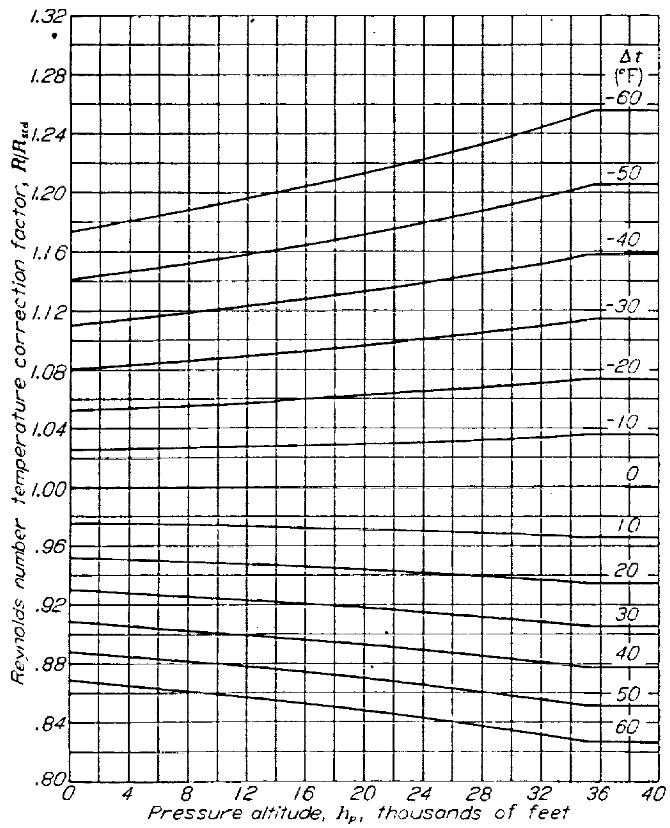


FIGURE 5.—Variation of Reynolds number temperature correction factor with pressure altitude and the deviation Δt of the free-air temperature from the temperature of the standard atmosphere.

PROPERTIES OF STANDARD ATMOSPHERE

For many purposes, such as performance and load calculations, the concept of a standard atmosphere has proved to be very useful. The United States standard atmosphere was officially adopted in 1925 (reference 6). In reference 6 tables are given that are of most use in the calibration of instruments. The properties of this atmosphere were originally tabulated by Diehl (reference 5).

Table VII gives the standard atmospheric values up to altitudes of 65,000 feet and includes quantities that have been found to be of use in the interpretation of airspeed and related factors. These quantities are the pressure in pounds per square foot, the pressure in inches of water, the speed of sound, the coefficient of viscosity μ, and the kinematic viscosity ν. All the quantities given in table VII are in the English system of units for every 500 feet of altitude up to 65,000 feet.

The values given in table VII for the coefficient of viscosity μ and the kinematic viscosity ν are not standard values since a standardization of air viscosity has not been agreed upon as yet. The values listed for μ and ν are believed to be sufficiently accurate, however, to be useful in calculations requiring viscosity of air.

For altitudes from sea level to 35,000 feet, the pressure p in pounds per square foot and in inches of water was determined from the ratio p/p_0 given in reference 5 and values of the pressure at sea level of 2116.2 pounds per square foot and 407.1 inches of water. The sea-level pressure in pounds per square foot is based on the pressure in inches of mercury at 32° F of 29.921. The sea-level pressure in inches of water is based on the pressure in inches of mercury at 32° F and water at 59° F. The pressure p in inches of mercury for altitudes up to 35,000 feet is taken directly from reference 5.

The quantities mass density ρ and density ratio σ are also taken directly from reference 5 for the altitudes from 0 to 35,000 feet. For altitudes over 35,000 feet the pressures, the mass density, and the density ratio were recalculated, since a minor error was discovered in the calculations of reference 5 for the pressure ratio for altitudes above 35,332 feet.

The quantity $1/\sqrt{\sigma}$ is given to facilitate the computation of the true airspeed V from the equivalent airspeed V_e.

The absolute temperature in degrees Fahrenheit was obtained from reference 5 except for altitudes above 32,000 feet, where interpolation was necessary at the 500-foot stations.

For ready reference, the standard values and the variation with altitude of temperature and density originally used in the computations for the standard atmosphere are included in appendix B of the present paper.

The speed of sound in miles per hour computed from equation (8) is given in table VII. A value of $\gamma=1.4$ was assumed to hold for the temperature range that is included in table VII.

The coefficient of viscosity μ was computed from the formula

$$\mu=\frac{2.318}{10^8}\,\frac{T^{3/2}}{T+216} \tag{27}$$

Equation (27) was obtained from reference 7 by converting the equation given therein to the English system of units and by starting with a value of $\mu=3.725\times10^{-7}$ consistent with the standard sea-level conditions.

The kinematic viscosity of air ν was obtained from the definition

$$\nu=\frac{\mu}{\rho} \tag{28}$$

TENTATIVE EXTENSION OF STANDARD ATMOSPHERE

The NACA Special Subcommittee on the Upper Atmosphere at a meeting on June 24, 1946, resolved that the tentative extension of the standard atmosphere from 65,000 to 100,000 feet be based upon a constant composition of the atmosphere and an isothermal temperature which are the same as standard conditions at 65,000 feet. This tentative extended isothermal region ends at 32 kilometers (approximately 105,000 ft). It is possible that as results of higher altitude temperature soundings become available and the standard atmosphere is extended to very high altitudes the present recommendation may be modified.

The Subcommittee also recommended that the values of temperature given in the following table be considered as maximum and minimum values occurring for the given altitudes with the variations between the specified points to be linear:

Altitude (km)	Temperature (°C abs.)	
	Minimum	Maximum
20	180	250
25	---	250
45	200	380

A tentative extension of the standard atmosphere computed from the equations given in appendix B using the recommended isothermal temperature is given in table VIII for altitudes from 65,000 to 100,000 feet. All quantities given in table VII are included in table VIII.

APPENDIX A

SUMMARY OF EQUATIONS RELATING AIRSPEED QUANTITIES

The equations relating the various airspeed quantities, which are given in the present paper, are as follows:

$$q_c=p\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho}{p}V^2\right)^{\frac{\gamma}{\gamma-1}}-1\right] \text{ for } V<a \tag{A1}$$

$$q_c=p_0\left[\left(1+\frac{\gamma-1}{2\gamma}\frac{\rho_0}{p_0}V_c^2\right)^{\frac{\gamma}{\gamma-1}}-1\right] \text{ for } V<a \tag{A2}$$

$$q=\frac{1}{2}\rho V^2 \tag{A3}$$

$$q=f^2q_c \tag{A4}$$

$$q=\frac{\gamma}{2}pM^2 \tag{A5}$$

$$\rho=\rho_0\frac{p}{p_0}\frac{T_0}{T} \tag{A6}$$

$$f=\sqrt{\frac{\gamma}{\gamma-1}\frac{p}{q_c}\left[\left(\frac{q_c}{p}+1\right)^{\frac{\gamma-1}{\gamma}}-1\right]} \tag{A7}$$

$$f_0=\sqrt{\frac{\gamma}{\gamma-1}\frac{p_0}{q_c}\left[\left(\frac{q_c}{p_0}+1\right)^{\frac{\gamma-1}{\gamma}}-1\right]} \tag{A8}$$

$$M=\left\{5\left[\left(\frac{q_c}{p}+1\right)^{2/7}-1\right]\right\}^{1/2} \tag{A9}$$

$$a=\sqrt{\gamma\frac{p}{\rho}} \tag{A10}$$

If a is in miles per hour and T is in degrees Fahrenheit absolute

$$a=33.42\sqrt{T} \tag{A11}$$

If a is in knots and T is in degrees Fahrenheit absolute

$$a=29.02\sqrt{T} \tag{A12}$$

If a is in miles per hour and T is in degrees Centigrade absolute

$$a=44.84\sqrt{T} \tag{A13}$$

If a is in knots and T is in degrees Centigrade absolute

$$a=38.94\sqrt{T} \tag{A14}$$

$$V=Ma \tag{A15}$$

$$V=f\sqrt{\frac{2q_c}{\rho}} \tag{A16}$$

$$V_c=f_0\sqrt{\frac{2q_c}{\rho_0}} \tag{A17}$$

$$V_e=V\sigma^{1/2}=V\sqrt{\frac{\rho}{\rho_0}} \tag{A18}$$

$$V_e(\text{mph})=760.9M\sqrt{\frac{p}{p_0}} \tag{A19}$$

APPENDIX B

CONSTANTS AND EQUATIONS FOR USE IN COMPUTATIONS OF STANDARD ATMOSPHERE

The values of the standard atmosphere given herein are based on the following values:

Sea-level pressure $p_0 = 29.921$ in. Hg
$= 407.1$ in. H_2O
$= 2116.2$ lb/ft^2

Sea-level temperature $t_0 = 59°$ F

Sea-level absolute temperature $T_0 = 518.4°$ F

Sea-level density $\rho_0 = 0.002378$ slug/ft^3

Gravity $g = 32.1740$ ft/sec^2

Temperature gradient $\frac{dT}{dh} = 0.00356617°$ F/ft

The altitude of the lower limit of the isothermal atmosphere 35,332 ft

Specific weight of mercury at 32° F = 848.7149 lb/ft^3

Specific weight of water at 59° F = 62.3724 lb/ft^3

Up to the lower limit of the isothermal atmosphere (−67° F corresponding to 35,332 ft) the temperature is assumed to decrease linearly according to the equation

$$T = T_0 - \frac{dT}{dh}h \tag{B1}$$

Further, the atmosphere is assumed to be a dry perfect gas that obeys the laws of Charles and Boyle, so that the mass density corresponding to the pressure and temperature is

$$\rho = \rho_0 \frac{p}{p_0}\frac{T_0}{T} \tag{B2}$$

In reference 5 the pressure and altitude are related by

$$h = \frac{p_0}{\rho_0 g m}\frac{T_m}{T_0}\log_{10}\frac{p_0}{p} \tag{B3}$$

where m is the modulus for common logarithms, that is,

$$m = \log_{10} e = 0.434294 \tag{B4}$$

The harmonic mean temperature T_m is given by

$$T_m = \frac{\Sigma \Delta h}{\Sigma \frac{\Delta h}{T_{av}}} = \frac{\Delta h_1 + \Delta h_2 + \ldots}{\frac{\Delta h_1}{T_{av_1}} + \frac{\Delta h_2}{T_{av_2}} + \ldots} \tag{B5}$$

where T_{av_1}, T_{av_2}, . . . are the average temperatures for the altitude increments Δh_1, Δh_2, ...

Positive directions of axes and angles (forces and moments) are shown by arrows

Axis		Force (parallel to axis) symbol	Moment about axis			Angle		Velocities	
Designation	Symbol		Designation	Symbol	Positive direction	Designation	Symbol	Linear (component along axis)	Angular
Longitudinal	X	X	Rolling	L	$Y \longrightarrow Z$	Roll	ϕ	u	p
Lateral	Y	Y	Pitching	M	$Z \longrightarrow X$	Pitch	θ	v	q
Normal	Z	Z	Yawing	N	$X \longrightarrow Y$	Yaw	ψ	w	r

Absolute coefficients of moment

$C_l=\dfrac{L}{qbS}$ (rolling) $\quad C_m=\dfrac{M}{qcS}$ (pitching) $\quad C_n=\dfrac{N}{qbS}$ (yawing)

Angle of set of control surface (relative to neutral position), δ. (Indicate surface by proper subscript.)

4. PROPELLER SYMBOLS

D Diameter

p Geometric pitch

p/D Pitch ratio

V' Inflow velocity

V_s Slipstream velocity

T Thrust, absolute coefficient $C_T=\dfrac{T}{\rho n^2 D^4}$

Q Torque, absolute coefficient $C_Q=\dfrac{Q}{\rho n^2 D^5}$

P Power, absolute coefficient $C_P=\dfrac{P}{\rho n^3 D^5}$

C_s Speed-power coefficient $=\sqrt[5]{\dfrac{\rho V^5}{P n^2}}$

η Efficiency

n Revolutions per second, rps

Φ Effective helix angle $=\tan^{-1}\left(\dfrac{V}{2\pi rn}\right)$

5. NUMERICAL RELATIONS

1 hp=76.04 kg-m/s=550 ft-lb/sec

1 metric horsepower=0.9863 hp

1 mph=0.4470 mps

1 mps=2.2369 mph

1 lb=0.4536 kg

1 kg=2.2046 lb

1 mi=1,609.35 m=5,280 ft

1 m=3.2808 ft

ABSTRACT:

Symbols and definitions are presented of various airspeed terms adopted as standard by NACA Subcommittee on Aircraft Structural Design. Equations, charts, and tables required in evaluation of true, calibrated and equivalent airspeeds, impact and dynamic pressures, and Mach and Reynolds Numbers are compiled. Tables of standard atmosphere up to altitudes of 65,000 ft and tentative extension to 100,000 ft altitude are given with basic equations and constants on which both standard atmosphere and tentative extension are based.

DISTRIBUTION: SPECIAL. All requests for copies must be addressed to Originating Agency.
